Reproduction of advertisement in January magazines

Now you can prescribe LIGHT for home application

THE Eveready Sunshine Lamp and Eveready Sunshine Carbons, two products of the National Carbon Company, Inc., have been designed to bring into the home for use at any time and any season all the essential rays of natural summer sunshine. Ultra-violet, visible and infra-red rays are reproduced in substantially the same proportions as are found in natural sunshine. This lamp gives physicians an opportunity to prescribe controlled sunlight which can be safely used at home in prevention and cure of rickets and other cases where sunlight is indicated.

As advertised and sold to the general public, however, the Eveready Sunshine Lamp is a producer of man's closest duplication of natural sunshine. Our advertising and literature not only avoids prescribing this man-made sunshine for treating diseases, but specifically directs the reader to consult his physician in case of illness, to avoid the dangers of self-diagnosis, and to use light only to build up health.

Regarding this conservative, ethical policy the Council on Physical Therapy of the American Medical Association had the following to say: "Your letter of July 2, 1928, outlining the proposed policy of National Carbon Company, Inc., was submitted to the Council for consideration. The policy therein outlined is acceptable to the Council."

Should the condition of any of your patients indicate the use of therapeutic light, as distinct from sunshine, you can instruct the removal of the glass filter in the lamp, and order the correct type of Eveready National Therapeutic Carbons, which are sold on physician's prescription only.

Write for booklets giving full details of the Eveready Sunshine Lamp, Eveready Sunshine Carbons, and Eveready National Therapeutic Carbons.

The U. S. A. is only a few minutes wide

An Advertisement of the
American Telephone and Telegraph Company

IN THE gold rush year of '49 a stagecoach succeeded in crossing the continent in about three months. Two decades later, for the first time, an unbroken stretch of railroad lay from New York Harbor to San Francisco Bay, and America was seven days wide. Today, by telephone, *that entire width is only* a matter of minutes. And these few minutes represent a round trip, taken in the ease of office or home.

The Bell System is ever busy reducing the width of America and the distance between cities. For example, during 1929 it will add to its lines nearly 2,000,000 of the new permalloy loading coils for correcting and maintaining the speeding voice currents.

Seven thousand miles of new intercity cable, $40,000,000 worth, will be added to the System to protect against storms and other slowing up influences.

In the last five years 350 major improvements, as well as thousands of others whose aggregate importance mounts high, have been made in telephone central office equipment.

Improved operating practices have eliminated the necessity of your "hanging up" and being called back *in 95 per cent of toll and long distance* calls, adding new speed and ease to out of town calling. You hold the wire and the operator does the rest.

Since New Year's Day, 1927, the average time for completing all out of town calls has been cut 35 per cent and at the same time the per cent of error has been further materially reduced.

There is no standing still in the Bell System. Better and better telephone service at the lowest cost is the goal. Present improvements constantly going into effect are but the foundation for the future's greater service.

LABORATORY SUPPLIES

STALKING THE FOOD FADDIST

It is time for common sense, aided by sane medical and scientific opinion, to put an end to dangerous dieting fads.

EMINENT doctors of medicine are making it hard for the food faddist to maintain his hold on the credulity of the American public. Dr. Morris Fishbein, in "Your Weight and How to Control It," says: "Of all the fads which have afflicted mankind, none seem more difficult to explain than the desire of American women for the barber-pole figure." Other authorities, in the same volume, warn of the permanent injury likely to result from starvation diets.

Dr. Solomon Strouse, Associate Professor of Medicine at Rush Medical College, in his address at the New York Academy of Medicine, as quoted by the *Evening World*, said: "I am beginning seriously to wonder whether scientific efforts at diet control based on animal experiment are not overshooting the mark; whether we are not interpreting the life of a caged white rat rather too seriously for the comfort of a free white man." He went on to say that "food and food habits in general play no important role in the attainment of longevity.... Despite much that I read of the evils of the modern way of eating and living, I find in actual practice comparatively few examples of excessive food indulgence to the point of harm. ... It is possible to conceive of undernutrition causing more trouble than overeating."

The trend of modern dieting thought is that human beings should not only eat a variety of healthful foods, but enjoy them. Yet few people will force themselves very long to eat foods that they do not like. As a food scientist says, "It is sugar which makes it possible for us to eat and enjoy the roughage foods, the vitamine foods, and foods rich in mineral salts." Fruit flavors are developed by sugar. Sugar facilitates the ingestion of fruits, cereals and vegetables.

An eminent biological chemist refers to sugar as "Nature's incomparable flavoring agent." "Sugar," he says, "is the thing which makes the deadly dullness of our overly refined foods palatable. Another thing, it is wholesome."

There is no substitute for sugar. Appetizing cookery revolves around sugar. The Sugar Institute, 129 Front Street, New York.

Progress!

"Established to promote public welfare by teaching the value of cleanliness"—such is the purpose of Cleanliness Institute.

What has been accomplished? Here in brief is the record for 1928, the first full year of the Institute's existence.

Cleanliness messages reached audiences in the tens of millions through the printed page, the microphone, and the cooperation of thousands of officials and organizations. *The aggregate circulation—or the number of times that cleanliness educational messages were repeated—reached the impressive total of 671,000,000.* This number, tremendous as it is, will probably be exceeded in 1929.

Outstanding among the activities of the Institute has been the publication of three graded supplementary school readers of unusual charm and value, written by authorities, well illustrated, pedagogically sound, aimed at inculcating habits as well as knowledge. These cleanliness stories and texts have been instantly popular with school administrators and teachers. School leaders have asked for hundreds of thousands of copies.

The cooperation of the Institute is yours for the asking. Gratifying progress has already been made. Even greater usefulness can result as interest increases among leaders of public thought and organization.

Are you in touch with the Institute? If not why not write today?

Beverages and their relation to health

IN a recent health survey, 83 mothers per 100 replied "yes" to the question, "have you found it necessary to warn your children about dangerous beverages, such as those containing artificial flavoring and coloring or drugs or other harmful ingredients?"

Furthermore, they stated that they had urged the children to change to Hires. There is a widespread awakening among parents as to their responsibility in directing the child as to *safe* beverages.

For over 50 years Hires has been recognized as a beverage of exceptional and unique merit.

Hires is made of the plant juices of 16 roots, herbs, barks and berries.

Hires is free from all harmful drugs—it does not contain caffein or artificial flavoring or coloring. Nor does it contain capsicum.

Hires may be had in three forms: At the fountain or in carbonated bottles or in Hires Extract for making Root Beer at home.

Hires is as appetizing as it is pure—a welcome beverage in millions of homes. Its ever-increasing popularity is undoubtedly due to its acceptance as a *protective* beverage.

FREE: A sample of Hires Extract for making Root Beer at home will be sent to any doctor or health officer upon request.

NUTRITION experts agree almost without exception on the necessity of a balanced diet. Any attempt to educate the layman on this subject must undertake a revision of many old-fashioned ideas.

One of these ideas is the notion that the eating of candy is a mere indulgence. For from the standpoint of nutrition, candy is a food. The problem of the nutrition expert is to get people to eat it sensibly, as part of a balanced diet.

We, the National Confectioners' Association, are conducting an educational campaign, urging the public to take a rational attitude toward candy, to consider it in proper relation to other foods. We invite suggestions for the improvement of the campaign from those professionally interested in public health.

A large number of technical men have written us. We would like to hear from a great many more. The writers do us a great service, and we believe do a service to the public.

Prevention *instead of* Prescription

Help keep from catching colds by washing your hands often, particularly before meals. This simple precaution is worth practicing at all times but especially now.

Excerpt from U.S.P.H.S. Influenza Commission report . . .

ing or spitting.
2. Special emphasis upon the need of washing the hands frequently, more especially before eating; unclean articles and fingers should be kept out of the mouth and nose. This advice is particularly applicable to all persons in attendance upon the sick.
3. Avoidance of exposure

Dirty hands are more likely than clean hands to transmit germs to the mouth, whether of colds or any other communicable disease. Clean hands, clean dishes, clean handkerchiefs, and clean clothes mean less colds, influenza and pneumonia.

If you have any responsibility in bettering health conditions, Cleanliness Institute has available helpful literature and pictures.

Getting there ahead of the trouble

An Advertisement
of the
American Telephone and Telegraph Company

DURING the afternoon of March 17, 1928, an alarm bell rang in a telephone test station in the heart of the Alleghany mountains. This meant that a puncture had been made in the air-tight sheath of a busy inter-city cable. The men on duty knew that the injury was somewhere within 50 miles.

Highly developed locating devices were instantly applied and in sixty-five minutes the trouble spot was located. By 7.15 in the evening, before the break in the sheath had affected service on any of the 248 pairs of wires in the cable, the repairs had been made. Because of the preliminary warning on the indicator wire and the locating devices that enabled the test station to tell the repair crew just where it would find the trouble, not one conversation was interrupted. This special alarm system is one of the many mechanical and electrical wonders developed by Bell System engineers to guard telephone conversations. The apparatus is placed along the cable routes at intervals of 100 miles. It gives instant warning day or night of any disturbance to the cable within 50 miles in either direction. Automatic warning signals, electrical locating devices, constant testing of all switchboard apparatus and circuits—these are some of the ceaseless efforts that so effectively reduced interruptions to service on Bell lines in 1928.

There is no standing still in the Bell System. Constant progress in accuracy and better service at the lowest cost is its goal.

Has Associated Himself with the Company in the Capacity of Managing Director

"Your products have been exclusively used by The Ohio Department of Health since 1924. In administering over 500,000 Schick Tests, and immunizing treatments for diphtheria prevention, the treatment of thousands of cases of diphtheria, prophylactic treatments for rabies, tetanus and vaccination for small pox, we have not had a single untoward incident. This experience indicates the safety of your products. Their efficiency is proved by the fact that not a single case of diphtheria has occurred in a Schick negative person. I will devote my entire time and energies to organization and consulting service to our patrons and the organization of research work."

Dr. JOHN E. MONGER,

In securing this management, the United States Standard Products Company now have at their head the ablest and most efficient management available in the Biological field.

Reproduction of the current magazine advertisement

SUNSHINE enters the home— but *not* for self-medication

HERE is a lamp that brings sunshine into the home. The Eveready Sunshine Lamp, burning Eveready Sunshine Carbons, produces a light containing all the essential rays of sunshine and in the same proportions as in the light from the summer sun.

If you wish to place your patients under therapeutic light, as distinct from sunshine, *you* can order the removal of the filter in the lamp and your patient can buy Eveready Therapeutic Carbons on *your* prescription. In our advertising to the public we emphasize that no attempt to correct any abnormal physical condition by light should be made without a physician's advice.

Regarding this careful, ethical policy the Council of Physical Therapy of the American Medical Association made the following statement: "Your letter of July 2, 1928, outlining the proposed policy of the National Carbon Company, Inc., was submitted to the Council for consideration. The policy therein outlined is acceptable to the Council."

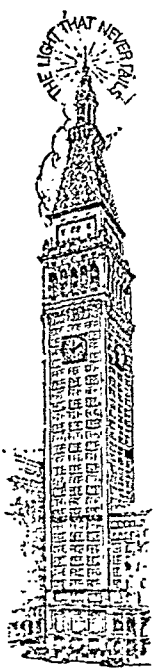
The "Left-behinds"

A SHORT time ago a business man, happily married and the father of two children, showed signs of failing health. A searching examination revealed tuberculosis. He was ordered to give up his business immediately and go to a sanatorium for proper treatment and care.

An uncle of the young man was greatly shocked when he heard the report. He asked for the evidence. They handed him x-ray photographs which showed that his nephew's lungs were seriously affected. The uncle asked permission to show the photographs to his own doctor.



When that doctor saw the photographs he said, "The right thing was done. Your nephew will probably get well. Now, what have you done for the man's family, especially the children? Have they been examined? You have no time to lose. While tuberculosis may not have made any serious inroads on their health as yet, it is hardly conceivable that his wife and children are entirely free from infection."

Every child who at any age has had prolonged exposure to tuberculosis should have an immediate, thorough physical examination, especially including the tuberculin tests and x-ray photographs, to determine whether or not active or latent disease is present. While tuberculosis usually attacks the lungs, it may attack any part of the body—eyes, ears, nose, throat, glands, joints, bones or vital organs.

It is now believed that many cases of tuberculosis in adults are the direct result of infection in childhood. The germs may have been taken into the body when the person was very young and have remained dormant for many years.

Boys and girls, apparently healthy, may have latent tuberculosis, without a sign of infection—no cough, no loss of weight, good color. But years later, when some extra strain is put upon the body, the symptoms appear—loss of weight, persistent cough, "indigestion" and fatigue.

When every child is properly fortified against the ravages of tuberculosis, the final victory over this deadly enemy will be in sight.

This year there will be a great forward step in the battle against tuberculosis. Efforts will be made to protect "the others"—the family and friends of the stricken person—even *before* the signs of tuberculosis show themselves, but while the disease may be latent.

Organizations for the prevention of tuberculosis—national, state and local—will warn people of the infection which may follow living in the same household or associating with one who has tuberculosis. Their action-inspiring slogan, "Early discovery—Early recovery," will be displayed on billboards, car cards and banners all over the country.

By checking tuberculosis in its earliest stages, before the germs have had time to destroy bone or tissue, tens of thousands of lives can be saved. Send for the Metropolitan's booklet, 4-J-9, "Tuberculosis". It will be mailed free on request.

What "UNIFORM TEMPERATURE" *means*

In incubation, the thermometric reading alone does not tell you the temperature history of your cultures, unless you know the ability of your incubator to maintain the same temperature over all usable shelf space.

Keep this in mind—a guarantee of "temperature control" (constancy of thermometric reading) means nothing without a similar guarantee of "uniformity" (correspondence of temperatures at various locations). The Cenco DeKhotinsky Triple Walled Incubator No. 7890 controls its thermometric temperature within a variable of 1/2° C. and maintains a uniformity of temperature over all the shelf space, top or bottom, within a variable of ±1.5° C. Stimulants, Sedatives or Food ~

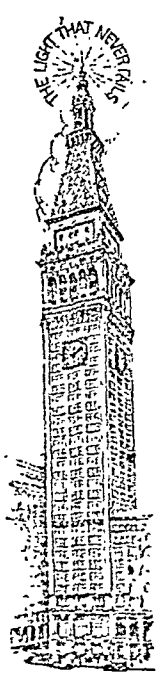
from a Health Standpoint

©1929, M.L.I.CO.



THE desire for extreme slenderness is bringing serious consequences. When stimulants, sedatives or drugs are substituted for the food needed to build health, the penalty is certain and severe—frequently broken health and sometimes death.

Half-truths are often more dangerous than falsehoods. While it is true that an excess of fat is frequently dangerous in the later years of life, it is not true that young people—under thirty years of age—can ordinarily expect to have good health if they avoid wholesome body-building foods and persist in a rigid "reducing" diet. There are certainly more cases of tuberculosis among young "underweights" than there are among those of normal weight.

During childhood and the early adult years, Nature demands a bodily reserve upon which she can draw to fight disease. In youth a few pounds of excess weight are a valuable protection against physical breakdown. The sacrifice of this needed tissue may result in permanent injury.

There is no mystery today in what constitutes an intelligent diet. The doctor who would not hesitate to prescribe a stimulant or a sedative in case of emergency, would forbid their use in place of needed foods.

A famous health expert was asked, "Do you think stimulants are harmful to everybody, no matter in what degree the stimulants are used?" He said, "Not always, but everyone should try to make himself so fit, physically, that he will not need or desire artificial stimulation. The hunger for stimulants is an indication of weakness and evidence of improper diet or other incorrect living habits."

Certain practices trick the appetite and dull the desire for food. When the demands of a normal appetite are too frequently denied, the appetite may be lost and food be made repugnant.

If the fathers and mothers of tomorrow will eat properly, exercise properly, work properly, sleep, breathe, stand, walk—yes—and *think* properly, they and their children will have better health and longer lives.

The Metropolitan Life Insurance Company has the privilege of consulting famous specialists on important health questions. While the Metropolitan wishes to point out most emphatically the danger of too strenuous dieting at the earlier ages, it also wishes to stress, no less emphatically, the danger of overweight at the older ages.

Our booklet, "Overweight," tells the best methods to control these evils. It also tells what you should weigh considering your age and height. Ask for Booklet 5A9—mailed free. Address Booklet Department, Metropolitan Life Insurance Company, New York, N. Y.

Planning high-speed business

An Advertisement of the
American Telephone and Telegraph Company

MORE than 95% of the telephone calls from one town to another in the Bell System are now on a high-speed basis. This holds whether the call is from New Orleans to Boston or from New York to Oyster Bay.

Even if it is a long call, the operator in many cases now asks you to hold the telephone while the call is put through.

Calls from one town to another used to be handled by one operator taking your order and giving it to another group of operators to put through. You now give your call direct to the operators who put it through — and put it through fast while you are on the line. The average time for handling all toll and long distance calls in the Bell System was further materially reduced in 1928.

A high-speed service to all parts of the country—calls from one town to another as swift, clear and easy as local calls—that is the aim of the Bell System.

This is one of the many improvements in methods and appliances which are constantly being introduced to give high-speed telephone service.

Better and better telephone service at the lowest cost is ever the goal of the Bell System.

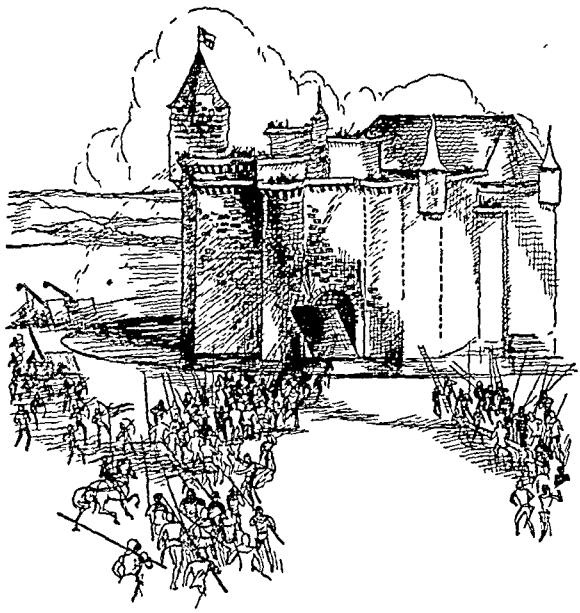
Here are the features of the

IMPROVED

B & L Hemoglobinometer

1. The photometric field can be perfectly balanced by virtue of a special blue filter in the eyepiece.

2. The color of the field is always the same, the two parts requiring to be matched in brightness only.



3. The light paths are exactly similar, and contain no cemented or silvered surfaces to absorb light.

4. No corrections for filter thickness are necessary.

5. The number of grams of hemoglobin per hundred cubic centimeters of blood is read directly from a scale from the eye position to 0.5 gram and estimated to 0.1 gram.

Keep the enemy out

[*a health idea, too*]

TO *prevent* invasion, they used to raise the drawbridge. It was a better idea than to grapple with actual invaders.

Today, departments of health are finding that to *prevent* the invasion of disease germs is a better idea than to fight them, once they are in.

Cleanliness Institute, in enlarging its Department of Health Service, aims to cooperate with health departments and organizations in showing how cleanliness can be used to fight disease.

The Institute makes available ideas, information, and assistance in this important field. Use these helps, which emphasize greater cleanliness, to enlist the public in your drive against communicable diseases.

Communicate with the Director of the Department, W. W. Peter, M. D., Dr. P. H., or with the Associate Director, W. R. Redden, M. D.

Where the sun doesn't shine

THE purifying rays of the sun do not always reach the more crowded city districts.

But the purification of *cleanliness* is available wherever people want it. In rich homes or poor, where the sun shines or where it doesn't, soap and water can perform their cleansing health task.

That is why health officials in their fight against disease are emphasizing more and more the simple, economical, *effective* program of cleanliness—a program by which *every citizen* can help protect himself, as well as others about him.

The causative organisms of 92 per cent of communicable diseases are transmitted through channels in which cleanliness is a most important preventive factor.

To assist Health Departments and organizations, Cleanliness Institute, through its Department of Health Service, makes available without expense, lectures, slides, ideas for literature, organization advice, and other aids.

For this assistance, write to the Department's Director, W. W. Peter, M. D., Dr. P. H., or to the Associate Director, W. R. Redden, M. D.

ARE YOU HANDICAPPED IN YOUR WORK WITH LIGHT?

THE PAST few years have brought forth outstanding accomplishments in the field of light therapy.

The marvelous work of Rollier with natural sunshine and that of Finsen with the carbon arc, both pioneers in their respective fields, has earned for them the recognition of the medical and scientific world.

Work with other artificial light sources has also come to the front and the whole demands the serious attention of all physicians who wish to know full value of light therapy.

The advent of Eveready Sunshine Carbons and the eight types of Eveready Therapeutic Carbons, interchangeable as they are in any arc lamp, offers the physician the greatest number of variations in wave lengths between the various bands from ultra-violet through the visible range to the infra-red of any artificial light source. The carbon arc lamp with Eveready Sunshine Carbons gives the closest approximation of natural sunshine.

The carbon arc with Eveready Sunshine Carbons or the proper type of Eveready Therapeutic Carbons is not limited to size of equipment nor to any specific bands in the spectrum. It can be adapted to give the physician a source of sunshine, ultra-violet or infra-red, for use in his office, in large hospital installations, and in the home. It offers him the widest range of light for his practice and his experimental work. It is the only light source which is complete in itself for all therapeutic work. Let us tell you more about it.

We cordially invite you to visit our exhibit. Booths Nos. 180, 181, 190, 191, at the annual convention of the American Medical Association at Portland.

Cancer—Ostriches

THE old notion that ostriches have the habit of hiding their heads in the sand in time of danger has been disproved again and again. Nevertheless the expression "hiding his head in the sand like an ostrich" aptly describes the man who seeks to avoid danger by refusing to recognize it when it comes.

© 1929 M. L. I. CO.

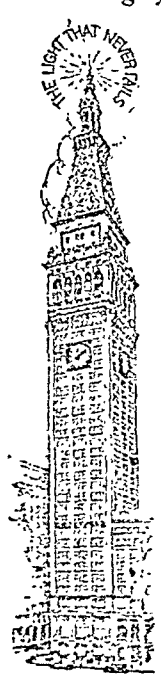
EACH year thousands of people die of cancer—needlessly—because they accept as true some of the mistaken beliefs about this disease.

No. 1—That every case of cancer is hopeless. *It is not.*

No. 2—That cancer should be concealed because it results from a blood taint and is disgraceful. *It is not.*

No. 3—That nature can conquer a malignant cancer unaided. *It can not.*

No. 4—That cancer can be cured with medicine, with a serum or with some secret procedure. *It can not.*



Many cancer patients are neglected or avoided because of the mistaken belief that cancer is contagious. *It is not.*

Be on Watch for First Signs of Cancer

Be suspicious of all abnormal lumps or swellings or sores that refuse to heal, or unusual discharges from any part of the body. Do not neglect any strange growth. Look out for moles, old scars, birthmarks or warts that change in shape, appearance or size.

If you have jagged or broken teeth, have them smoothed off or removed. Continued irritation of the tongue or any other part of the body is often the beginning of cancer trouble.

In its early stages, various kinds of cancer yield to skilful use of surgery, radium or x-rays. But the best doctors in the world are powerless unless their aid is sought in time.

Beware of Plausible Quacks

Because the nature and origin of cancer are largely shrouded in mystery, quacks and crooked institutions reap a cruel harvest. They prey upon the fear and ignorance of those who do not know the facts concerning cancer. They are often successful in making people believe that they have cancer when they have not. Later, with a great flourish, they boast of their "cures".

Gratefully the patients of the fakers, first thoroughly alarmed, later entirely reassured, are glad to sign testimonials with which new victims are trapped. Beware of those who advertise cancer cures.

An annual physical examination by your family physician, or the expert to whom he sends you, may be the means of detecting cancer in its early stages. Do not neglect it.

Thousands of improvements in central office equipment in 5 years

An Advertisement of the
American Telephone and Telegraph Company

IN THE last five years there have been hundreds of improvements of major importance in telephone central office equipment in the Bell System, and lesser improvements by the thousands. Improvements have been made in switchboard cable, in relays, in cords, in condensers, in selectors, and in the development of new and better materials for all kinds of equipment used in the central offices.

These improvements have not only helped to meet the steadily increasing complexity of telephone requirements. They also make possible the high-speed service which is eliminating delay from the personal contacts of people anywhere in the United States, whether they be separated by three floors of a building or three thousand miles of country.

There is no standing still in the Bell System. Better and better telephone service at the lowest cost is the goal. Present improvements constantly going into effect are but the foundation for the greater service of the future.

Only 28 states require this . . . *does yours?*

IN a recent investigation of state laws and regulations on cleanliness, James A. Tobey, L.L.B., Dr. P.H., found that only 28 states require barbers to wash their hands and sterilize their instruments before serving each customer. Dr. Tobey's report also revealed lack of sanitary regulation in a variety of other public institutions—restaurants, hotels, swimming pools, schools, etc., all of which can be sources of communicable disease.

Why not study the sanitary laws and regulations of *your* locality? And take steps to raise the requirements where necessary?

Write to Cleanliness Institute. We are prepared to cooperate.

Policing the Mouth, an illustrated cleanliness lecture, is now available on a loan basis to health officers. This lecture shows how a higher standard of cleanliness helps prevent communicable diseases from entering the system through the mouth.

It is written in simple, convincing, conversational style by W. W. Peter, M.D., DR. P.H., Director of Cleanliness Institute's Department of Health Service. It is illustrated with many fascinating slides. It is packed full of compelling statistics and facts.

Many health officials are already using *Policing the Mouth* in their educational and preventive programs. If you would like to do so, please write to the Department of Health Service.

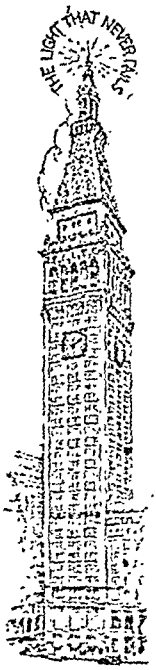
Common Sense

A FAMOUS doctor, said, "Many of the people who want me to diagnose and treat their ailments are more impressed by some scientific medical apparatus than by plain, common sense advice. And they are more willing to follow orders faithfully if given some special office treatment.



"Recently a man I know well came in looking haggard. I gave him a thorough physical examination while inquiring about his living habits. The diagnosis was clear but the patient a problem. If I had told him the simple truth that what he needed most to get back his health and strength was to slow down, sleep more, and get the proper amount of fresh air and exercise, he would have thought I did not understand the complications which were undermining his health. And if I had sent him a bill for such advice, he would have told his friends that I was a robber and not fit to practice medicine.

"So I gave him a treatment with a scientific apparatus and wrote a simple prescription. At the same time I gave strict orders as to what he should eat and drink, how many hours he might work, how long he should remain in bed, and the amount of time he should devote to outdoor exercise. To make sure that he was following my orders concerning his living habits, I had him report once a week for further observation and treatments. In a few weeks he was well. He will tell you—and he believes it—that I am a great doctor.

"Perhaps someone may say my methods with him were open to criticism. But it was my responsibility to use every means within my power to bring him back to good health. Knowing my patients as I do, I know that many of them will not obey my orders for *correct living habits* if given without special treatment or medicine. More than half of the people who consult me would not have to do so if they would learn and practice important rules of health. They expect me to cure them of physical ailments which they could easily have avoided."

A majority of cases of physical let-down and distress are caused by careless or wilful violation of health rules. Bad eating habits, too little sleep and rest, lack of fresh air and exercise, worry, self-pity are responsible for many cases of bad digestion, headaches, poor circulation, constipation, jumpy nerves, depression and run-down condition.

* * * *

The Metropolitan Life Insurance Company has had a booklet prepared by eminent health experts which tells simply and clearly the fundamental rules of intelligent living habits. A chapter or more is devoted to each one of eleven important rules of health under the headings Sleep and Rest, Fresh Air, Sunlight, Exercise, Cleanliness, Water, Food, Comfortable Clothing, Work and Play, Good Posture and Good Mental Habits.

NOTHING LESS THAN

SPENCER

PRECISION SLIDING

MICROTOME No. 860

Statement

made by a Professor in one of America's greatest universities. He had *one* of these microtomes and bought *two* more.

I. It is a precision Microtome, feeds automatically and cuts to two microns.

II. It cuts sections of ACCURATE thickness, one after another of the same thickness, not only of the usual soft tissue but wood sections and hard tissue usually found very difficult to cut on any microtome.

III. It will cut sections of large size 3¼ inches—one after another until 1¾" of the object is consumed without necessity of raising the object and resetting the feed for further sectioning.

IV. It is built of heavy frame 14" long and 7" high, carrying a bed for the sliding block of 16" length; a knife support holds the knife rigidly in one plane while moving to and fro. A substantial ball and socket object clamp is fed upward by a feeding mechanism of unvarying accuracy.

When writing to Advertisers, say you saw it in the JOURNAL

Provides flush closure because of a specially designed flange which can be built into the linings of Cherry Twin Coil Pasteurizers. Two deep grooves in the plug provide drip escape. Steam sterilization is not necessary.

NEW CHERRY-BURRELL FLUSH VALVE

SEVERAL years ago health officers pointed out the dangers of dead ends on pasteurizing equipment. They wanted a flush closure right at the inner wall of the container. Seepage into the milk line had to be prevented by a second valve seat. Drip escape and steam sterilization devices were necessary to take care of the unpasteurized seepage.

Equipment manufacturers soon developed delicate flush valves—complicated—intricate in design—to meet these needs.

However Cherry-Burrell engineers were not satisfied, chiefly because they knew that operators would be careless with the delicate valve seats. Stems were bent and valve seats scored in the wash tanks. Dissatisfaction reigned.

Now a flush valve is offered which eliminates all the evils of the first efforts. It provides flush closure. It allows the escape of any seepage through the deep grooves cut into the valve body. Dead ends are eliminated. It meets every requirement, yet is simple and sturdy in construction.

This revolutionary valve is now standard on all Class K and KV Cherry "Twin Coil" Pasteurizers and Ripeners. It cannot be installed on machines now in the field.

This new valve was first exhibited at the American Public Health Association Convention in Chicago during October, 1928. Every Health Officer and Milk Inspector who saw it favored its adoption. It is now standard and can be obtained on the above machines.

...IT CONTRIBUTES TO THE PROSPERITY OF THE PEOPLE AND TO THE COMFORT AND CONVENIENCE OF LIVING

The telephone grows with the country

An Advertisement of the American Telephone and Telegraph Company

THE Bell System must march a pace ahead of the new civilization on this continent, a civilization of better opportunity for the average man. The telephone contributes to the prosperity of the people and adds to the comfort and convenience of living.

It is used by the many. The time and money it saves are as important to the small business as to the large. The humblest home depends on it for aid in emergency, to run errands, maintain friendships. It is the aim of the Bell System to keep telephone service so good and so cheap that it will be used universally to make life richer and better. It seeks to lead the way in social and business growth. It is raising buildings this year in more than two hundred cities, adding vast mileage to the expanding network of cable, and installing new telephones by the hundreds of thousands.

It is spending more than 550 million dollars this year—one and one-half times the cost of the Panama Canal—for new plant and service improvements. This program is part of the telephone ideal that anyone, anywhere, shall be able to talk quickly and at reasonable cost with anyone, anywhere else. There is no standing still in the Bell System.

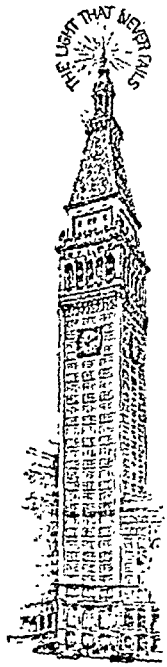
Bausch & Lomb Optical Co.

684 St. Paul St. Rochester, N. Y.

HOW would you feel if you could not read the news of the world? No newspapers, magazines, books, letters, not even a danger sign or a warning notice?



Somewhere near you is a grown person groping in the dark, in many ways helpless as a child, because he cannot read or write. You can bring sunlight into his darkened life. More than that, you may be the means of bringing him better health—even of saving his life.

"Thank God! At last I'll be able to read and write."

Today he cannot read messages on disease prevention. He does not know, unless someone tells him, the important rules of health or how to keep his family from having diphtheria, smallpox or typhoid fever. These and other preventable diseases often make illiterate localities their breeding places and thus endanger the health of the educated, despite all their precautions.

Perhaps you share the mistaken belief that it is impossible to teach grown-up illiterates how to read and write and that they are content to be illiterate.

Get the confidence of an illiterate and ask him if he would like to be able to read and write. Tell him he can learn to write his name in 30 minutes and learn to read in a few months. In all probability his eager response will amaze you.

It may surprise you to learn that the majority of illiterate persons in the United States are native born—more than three million illiterate Americans. Many of them have never had a chance to learn and do not know where to look for instruction.

Illiterates are not hard to find—a servant, a farmhand, an employee in your own or a neighbor's shop, a laundress, a deliveryman, a laborer in your neighborhood.

There are more than 5,000,000 men and women in the United States who cannot read health messages concerning sanitation and prevention of disease—more than 400,000 of them are in the State of New York, more than 300,000 in Pennsylvania, about 150,000 in Massachusetts. You can find them in every State of the Union—in cities, in towns and in country districts.

Will you give someone a present that he would not exchange for hundreds of dollars—the ability to read and write—a present which costs you nothing?

Find *your* illiterate. If you will help him to learn to read and write, the Metropolitan Life Insurance Company will send you, free of cost, grooved writing pads and illustrated lessons for beginners.

Ask for Booklet 9A9.

The line of defense

. . . let cleanliness protect the home against enemies to health

When you come to think of it, the clothes line is much more than a piece of rope stretched between two poles.

It is a real *line of defense!*

Cleanliness . . . both personal and environmental . . . is one of health's greatest allies, in that it presents a barrier against the entrance of disease germs into the human body. And clothes that are *kept* clean by frequent thorough washing, are an important part of the cleanliness practices of the family.

Cleanliness Institute's Department of Health Service studies cleanliness in relation to human welfare. It offers Health Departments and organizations valuable cleanliness material: for example, lectures, slides, ideas for literature, advice for popular education. Communicate with the Department of Health Service.

CLEANLINESS INSTITUTE

THE warning signs, "Stop, Look and Listen," have become merely a part of the roadside landscape to many an automobile driver. Heedlessly he passes ten, twenty—perhaps fifty of them—safely. At the fifty-first comes the crash.

Last year 8,383 persons were killed outright or injured in automobile accidents at grade crossings in the United States. There are about 235,000 grade crossings in the country; more than 93% of them are unprotected.

With millions of new automobiles on the roads each year, accidents at grade crossings are increasing at an alarming rate, for the reason that most of the States have no organized program for protecting motor traffic which must cross railroad tracks.

New York, under wise leadership, has shown how to solve the problem. Before the Empire State adopted her present plan, but 10 crossings a year, on an average, were done away with. This year, the first in which the railroads, the State and communities have co-operated—the railroads paying 50% of the cost, the State 49% and communities 1%—85 death-traps are marked for immediate removal. Next year New York hopes to eliminate 150 of its worst danger spots.

Other States are becoming aroused to this terrible and needless destruction of life and property and are taking steps to prevent it. Canada, too, is taking action.

It will require many years to complete the work. It is estimated that it will ultimately cost twelve billions of dollars. But what railroads and States and communities ought to do is to begin at once with those grade crossings which should be abolished first.

Grade crossings are dangerous not only to automobilists and pedestrians, but to people who are traveling on trains. The first section of a limited train struck an automobile and killed two persons. The train stopped and the second section plunged into it, killing thirty-two passengers in the first section.

Wherever the law provides facilities for eliminating grade crossings, citizens should see that public officials perform their duty and abolish these death traps. Wherever the laws must be amended, people should meet the issue squarely and urge prompt action by legislative bodies.

There is danger at every grade crossing. Get rid of them. Copy of New York's progressive program will be mailed free on request. Address, Department 10A9.

STERILIZING ATTACHMENT SHOWING CHLORINE TANK AND PUMP

BACK VIEW OF LADD'S STANDARD PRESSURE WASHER

ABSOLUTE STERILIZATION OF MILK AND CREAM BOTTLES WITHOUT STEAM!

LADD'S Standard, Big Six and Junior Pressure Washers — those already in service as well as new ones — may be equipped with a Chlorine Sterilizing Attachment which permits the absolute sterilization of milk and cream bottles without the use of live steam.

A strength of 50 parts of free chlorine to 1,000,000 parts of water will destroy all bacteria in less than one minute. The use of this perfected Chlorine Sterilizing Attachment assures positive sterilization where hard water conditions render low temperatures desirable and has the further general advantage of delivering a cold bottle to the filler.

Meet us at Toronto October 21 to 26

Ask us for Bulletin No. 65 which describes this attachment and the great line of LADD'S Washers.

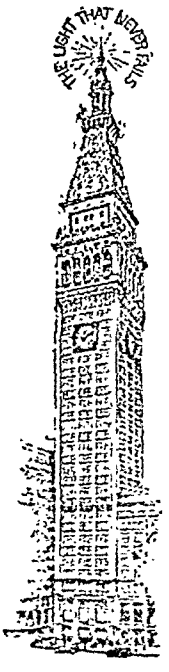
Lucky Babies



LUCKY indeed is the baby who has a mother wise enough to follow the doctor's advice—"Bring the baby to me when he is six months old and let me protect him against diphtheria. That is one disease he need never have."

Last year more than 100,000 children who were not inoculated had diphtheria. About 10,000 of them died—an average of more than one every hour of every day in the year.

Will 10,000 innocents be sacrificed next year because some doctors have failed to warn mothers or because mothers have forgotten their doctors' warning?

Even when diphtheria is not fatal, it frequently leaves its victims with weakened hearts, damaged kidneys, ear trouble, or other serious after-effects. The majority of deaths from diphtheria are of little children less than five years old. If your child, so far unprotected, has not been stricken by this arch-enemy of childhood, your good fortune is a matter of luck—not precaution. If he is more than six months old, take him to your doctor without delay and have him inoculated.

Diphtheria can be prevented by simple, painless inoculation which is lasting in its effect. Call up your doctor now and make an appointment.

Prevention of diphtheria through inoculation with toxin-antitoxin should not be confused with *treatment* of the disease by means of anti-toxin. The latter is a cure—the former prevents.

This disease has practically disappeared in many cities where the people have backed their health authorities in preventing diphtheria by inoculation with toxin-antitoxin. But diphtheria finds its victims wherever people have been misled by false reports as to the alleged danger of inoculation or have not learned to seek the protection which inoculation gives.

The Metropolitan Life Insurance Company will gladly cooperate through its local managers, agents and nurses, with State or city authorities to stamp out diphtheria. Detailed reports showing how various cities organized their successful campaigns for "No More Diphtheria" will be mailed free of charge. Ask for Booklet 11A9.

800,000 ADDITIONAL TELEPHONES ARE GOING INTO USE THIS YEAR

A million and a half dollars a day

An Advertisement of the
American Telephone and Telegraph Company

MORE than 200 new Bell telephone buildings are going up this year in the United States, 800,000 additional telephones are going into use and new switchboards to care for 3,000,000 additional calls a day. Thousands of miles of new cable, millions of miles of wire, new carrier systems, vacuum tubes and loading coils.

These are a few of the things in the 1929 construction and improvement program of the Bell System which will cost more than 550 million dollars—a million and a half a day.

Telephone growth is essential to the new American civilization of better opportunity for the average man. The Bell System employs more than 400,000 workers, is owned by 450,000 stockholders and serves the people of the nation.

Every day the Bell System is extending its lines to more people, increasing the speed and accuracy of its service, giving greater comfort and convenience in telephone use. All of this is done that each individual may get the most from this means of all inclusive and instantaneous communication and that the nation may be one neighborhood.

This is part of the telephone ideal that anyone, anywhere, shall be able to talk quickly and at reasonable cost with anyone, anywhere else. There is no standing still in the Bell System.

NOTHING LESS THAN

SPENCER

PRECISION SLIDING MICROTOME No. 860

Statement made by a Professor in one of America's greatest universities. He had *one* of these microtomes and bought *two* more.

I. It is a precision Microtome, feeds automatically and cuts to two microns.
II. It cuts sections of ACCURATE thickness, one after another of the same thickness, not only of the usual soft tissue but wood sections and hard tissue usually found very difficult to cut on any microtome.
III. It will cut sections of large size 3¼ inches—one after another until 1¼" of the object is consumed without necessity of raising the object and resetting the feed for further sectioning.
IV. It is built of heavy frame 14" long and 7" high, carrying a bed for the sliding block of 16" length; a knife support holds the knife rigidly in one plane while moving to and fro. A substantial ball and socket object clamp is fed upward by a feeding mechanism of unvarying accuracy.

Leak Detector Valve with Sterilizing Chamber which can be furnished on all new Burrell Spray Pasteurizers.

DO YOU BELIEVE *in a* SAFE MILK SUPPLY?

IF you are interested in a safe milk supply you have heard of the demands made by health authorities that all seepage of milk be allowed to escape from the pasteurizer outlet fitting. This precaution is vitally necessary to keep all unpasteurized or partially pasteurized milk from entering the sanitary lines which conduct the pasteurized milk to the bottle filler and capper.

The leak detector valve illustrated prevents any leakage or seepage from entering the sanitary lines. Two grooves at the sides of the valve plug allow the leakage to escape. *It is absolutely impossible* for milk to pass unless the valve is open.

And as an extra precaution the valve has a steam jacket around the outlet. By admitting steam into this chamber the milk in the pasteurizer outlet is heated to the pasteurizing temperature.

These two safety measures can be provided on all new Burrell Spray Pasteurizers by specifying a Leak Detector Valve with sterilizing chamber.

An especially designed valve for use on Burrell Spray Pasteurizers in the field can also be furnished. If interested address the nearest Cherry-Burrell office or our headquarters office at Chicago.

When Age Chuckles

© 1929 M. L. I. CO.

"YOU *are the youngest looking grandfather I ever saw. What's the secret?*" "*My dear, two things The good health that I have worked for and won—and a keen interest in life. With books, music, sports, travel, inventions—each day brings something new. I want to see what will follow the telephone, radio, automobile, aircraft —what electricity will do next. . . .*"

No longer do scientists accept the idea of a fixed "span of life". They know that the average length of life is longer in some countries than in others. They know that babies fare more safely in the world—that people everywhere face fewer dangers today from contagious and other diseases.

While the average length of life has increased by 10 years since 1901, the improvement has been achieved mainly among the younger ages, leaving as our most pressing problem the protection of the lives of those who have already passed middle age.

One by one the perils which formerly caused untimely deaths are being conquered. "Witches" are not burned nowadays to stop plagues. On the other hand, sanitation, vaccination, inoculation and other scientific means are employed to prevent most of them.

People are learning the effect of fresh air, sunshine, cleanliness, proper breathing and exercise, sleep and a well-balanced diet.

An annual medical examination for the discovery and correction of physical impairments before they have progressed too far to be remedied will keep the body sound.

In the United States and Canada there are more than 2,500,000 people between 70 and 80 years of age; more than 600,000 between 80 and 90; fifty-odd thousand between 90 and 100; and about 5,000 past the century mark.

The person who plans wisely to live to a happy and ripe old age never forgets that the mind is a powerful influence and that physical troubles are apt to follow a morbid viewpoint.

The world is tingling today with promise of future marvels even more wonderful than those we now know. Live to enjoy them.

HELLIGE COLORIMETRIC COMPARATORS

For Hydrogen Ion and Other Colorimetric Determinations

Employ Permanent Non-Fading Glass Standards

18005.

Dependence on standard color solutions which are apt to change more or less in the course of time is avoided. The glass standards are arranged in circular discs, each having 8 to 10 standard plates for a given indicator matching the pH value in steps of 0.2 pH.

Price of outfit, including 1 disc and 1 indicator solution 35.00

The Hellige Pocket Comparator is a smaller outfit, using the same color discs (see cut), but not including prism and acid-proof glass cells, test tubes being used instead of the square cells.....17.50

For water works the color scale for the Chlorine test is recommended.

Write for Bulletin No. 406 and additional details.

The Weather and the Common Cold*

THOMAS J. DUFFIELD

Executive Secretary, New York Commission on Ventilation, New York, N. Y.

IT IS the object of this paper to set forth in greater detail than has been done[1,2] the apparent relationships between the weather and the minor respiratory illnesses, commonly described as colds, as reflected in the absences reported due to this cause in three groups of school pupils during a part of the school year 1926–1927. These groups are:

1. Pupils of grades 2 to 6 in 2 mechanically ventilated schools (Danforth and Seymour) at Syracuse, N. Y.
2. Pupils of grades 2 to 6 in 2 naturally ventilated schools (Merrick and Montgomery) at Syracuse, N. Y.
3. Pupils of 48 rooms in one- and two-room rural schools in school districts 1 and 2 of Cattaraugus County, N. Y.

In the autumn of 1926, the New York Commission on Ventilation inaugurated a series of investigations of the effects of air conditions in school classrooms on the health of the pupils. During the school year 1926–1927, such studies were conducted in 3 mechanically ventilated and 3 naturally ventilated schools in Syracuse, and in 48 one- and two-room rural schools of Cattaraugus County, N. Y.

The incidence of respiratory illness among the pupils was taken as the criterion for judging the healthfulness of the air conditions in the classrooms. It was not possible to arrange for sufficient medical or nursing service either to make the determinations in the classroom or to make the necessary home visits, and, consequently, the cause of absence as reported by the parents constituted the source of information as regards absentees. The teachers recorded their own impressions concerning the prevalence of colds among the pupils in attendance at each session. The teachers also recorded four times each session the temperature as indicated by a reliable thermometer in a typical location in each classroom.

* Report to the Committee on Public Health Climatology, delivered before the Vital Statistics Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

In the Syracuse schools, differences of age and race stock of pupils were taken into consideration and eliminated as nearly as possible by limiting considerations to similar groups exposed to the different conditions created by the two types of ventilation. With this restriction, the observations in the Syracuse schools here reported relate to the pupils in grades 2 to 6, inclusive, in 2 mechanically ventilated schools —Danforth and Seymour—and in 2 schools with natural ventilation —Merrick and Montgomery.

Both boys and girls are registered in all these classes, the distribution by sex being approximately equal. The average age of the pupils in the 2 mechanically ventilated schools was 10.0 years, and in the 2 naturally ventilated schools 9.5 years. The percentage of pupils of American parentage was 71 in the mechanically ventilated schools, and 76 in the schools with natural ventilation. The number of pupils in the 2 mechanically ventilated schools was 1,086 and in the naturally ventilated schools 557.

The Syracuse study commencing November 29, 1926, and ending April 14, 1927, covered a period of 19 school weeks. It had been in progress but 4 weeks when it was interrupted by the Christmas holidays. Three weeks after these holidays were over, attendance was irregular because of the semi-annual examinations, and in the following week, the first of the second term, the records do not present an adequate picture of conditions because pupils who had not registered were not counted absent. In view of these irregularities and interruptions, it has been felt that for the purposes of this paper, consideration of these data should be limited to the period of 11 weeks from January 31 to April 14, 1927.

In the one- and two-room rural schools of Cattaraugus County, the number of pupils in the various schools was so small (the average being 18) and the pupils of foreign parentage so few in number that no attempt has been made to correct the data for these differences. Both boys and girls are registered in all these schools, which, giving elementary instruction only, are attended by pupils of approximately the same average age. The total number of pupils in the 48 classrooms was 860, and on the average (the records did not all commence and end at the same time) the study covered a period of 13 weeks of school.

In addition to studying the relationship between the types of ventilation, the air conditions in the classrooms and the incidence of colds among the pupils, the findings in each of these studies were also examined with reference to the outdoor temperature and precipitation, the weather data being taken from the records of the U. S. Weather Bureau.

DEFINITION OF TERMS

Mechanical Ventilation—Ventilation effected by means of mechanically driven supply and exhaust fans with appropriate ducts to and from each room, designed to provide each pupil with 30 cubic feet of air per minute.

Natural Ventilation—Ventilation by means of natural forces in which air change in rooms is dependent upon and effected by the difference in density of warm and cold air, and by wind direction and pressure.

Respiratory Illness—Coryza, pharyngitis, tonsillitis, laryngitis, bronchitis, pneumonia, grippe, etc. Except in those cases where a physician made the diagnosis, these terms were interpreted as cold and (or) sore throat.

Respiratory Illness Absenteeism—Absenteeism due to the above causes, expressed as a percentage of the total pupil-sessions for which the pupils were registered.

Indoor-Outdoor Temperature Difference—In order to facilitate the study of the association between outdoor temperatures and the incidence of respiratory illness among school pupils the temperature curve has been inverted. For Syracuse, the weekly mean of the outdoor temperature at 8 A.M., at noon, and at 4 P.M. on school days has been subtracted from 70° F. (the average indoor temperature).

In Cattaraugus County, where hourly outdoor temperature readings were not available, the weekly mean of the maximum and minimum temperatures has been subtracted from 70° F.

The inverted temperature curve thus shows the difference between indoor and outdoor temperatures at times when such differences, together with the conditions in the classrooms, might have a bearing on the incidence of respiratory illness among the pupils.

Precipitation—Precipitation is expressed in terms of inches of rain and (or) melted snow. In these studies precipitation has been grouped in 6 different ways, as follows:

1. Total precipitation for the 7 days ending on the Friday of the school week.
2. Precipitation on the 5 school days of the week.
3. Precipitation on the 5 school days of the week plus that over the preceding week end when such precipitation was in the form of snow.
4. Total precipitation for the 7 days of the week ending Wednesday.
5. Precipitation for the 5 school days of the week ending Wednesday.
6. Precipitation for the 5 school days of the week ending Wednesday plus that on Saturday and Sunday when such precipitation was in the form of snow.

FINDINGS

A. Syracuse

Table I shows the rates of absenteeism reported due to respiratory illness in the two groups of schools for the entire period of the study.

The mean outdoor temperatures for (1) the entire week, (2) on school days, (3) 8 A.M., noon, and 4 P.M., on school days, and (4) the daytime indoor-outdoor-temperature difference, on school days, are shown in Table II.

In Table III are given for each week: (1) the total precipitation for the 7 days ending Friday, (2) the precipitation on school days only,

4. Merrick and Montgomery schools

and (3) the precipitation on school days plus that over the preceding week end, when such precipitation was in the form of snow.

Table IV gives information similar to that in Table III, but in each case the period for which the precipitation is given ends on Wednesday. The essential data presented in Tables I to IV are shown in Figure I.

Coefficients of correlation between the respiratory illness absenteeism, temperature difference and precipitation have been calculated. The important ones are given in the Summary of Findings.

In addition to the demonstration of association between the variations in respiratory illness absenteeism in the mechanically ventilated schools with precipitation, and the apparent lack of relationship between the variations in the absenteeism due to this cause and the variations in outdoor temperature, by means of correlation, these same facts are brought out in a striking manner in Table V.

Of the 5 weeks in which the indoor-outdoor temperature difference exceeded the trend, i.e., weeks that were colder than the average, only 3 correspond with weeks in which the rates of respiratory illness absenteeism in the mechanically ventilated schools exceeded their seasonal trend, whereas each of these 5 weeks corresponds exactly with the weeks in which the precipitation on school days of the week ending Wednesday, plus the week-end precipitation when such precipitation was in the form of snow, exceeds the mean.

It is interesting to note that during the coldest week of the period (that ending March 4) the respiratory illness absenteeism was but 0.1 per cent above the trend value, and for the 2 weeks following (when the precipitation was low), such absenteeism was not in excess of the

trend. Low outdoor temperatures of themselves did not appear to be associated, either immediately or remotely, with increased respiratory illness among the pupils in these schools.

In Table VI, the excesses of temperature difference and precipitation are shown, together with the excesses of respiratory illness absenteeism in the 2 naturally ventilated schools in the Syracuse study.

In this case, of the 6 weeks in which the respiratory illness absenteeism is in excess of the general trend, only 2 correspond with weeks when the outdoor temperature was below the seasonal trend, whereas excessive precipitation occurred in 4 of these 6 weeks. There was, then, it appears, a closer relationship between precipitation and respiratory illness absenteeism in these schools than between such absenteeism and low outdoor temperatures.

B. Cattaraugus County

Table VII shows the mean outdoor temperature, the mean indoor-outdoor temperature difference (70° F. minus the mean outdoor temperature), the absenteeism reported due to respiratory illness and the total precipitation for each week of the study.

Inasmuch as the study of the relation between weather conditions and the incidence of colds among the pupils was supplementary to the investigation of the effects of air conditions in the schoolrooms—there being no essential difference in the method of ventilation of the various schools and consequently no attempt to demonstrate a differential effect of outdoor weather conditions under different methods of ventilation, as was the case in Syracuse—the weather data presented in Table VII relate to the entire week ending Friday and are not restricted simply to school days.

This information was taken from the reports of the U. S. Weather Bureau and is based on temperature observations at the Allegany State Park and on the precipitation recorded at Olean, N. Y. Both of these points of observation are within Cattaraugus County and are the Weather Bureau stations nearest the schools included in the study.

Maximum and minimum temperature readings are taken but once daily, and this prevents the detailed consideration of daytime temperatures that was possible for Syracuse where the hourly observations are available.

Similarly, differentiation is not made in the published reports of the data furnished by the coöperative observer at Olean between precipitation in the form of snow and that as rain. Much of the winter time precipitation in Cattaraugus County is snow which remains on the ground for considerable periods, and the pupils have to go through it morning and night on their way to and from school.

The information given in Table VII is presented graphically in Figure II.

TABLE VII

TEMPERATURE DIFFERENCE, PRECIPITATION AND RESPIRATORY ILLNESS ABSENTEEISM IN ONE- AND TWO-ROOM RURAL SCHOOLS—CATTARAUGUS COUNTY, N. Y., 1926–1927

15	37	33	3.6	0.00

Examination of this chart shows that the general trends in the two curves of temperature difference and of respiratory illness absenteeism are of the same character, but the fluctuations of the latter do not closely correspond with variations in the temperature difference. It will be seen, however, that, with but one exception, whenever the precipitation exceeds the mean, the following week shows an excess of respiratory illness absenteeism. See Table VIII.

Comparison of the data in columns 1 and 2 of Table VIII shows that of the 7 weeks in which temperatures were below the seasonal

average (trend line), only 4 correspond with weeks in which the respiratory illness absenteeism is above the average trend. On the other hand, 5 weeks which show an excess of respiratory illness have outdoor temperatures above the average. What is perhaps more striking is the fact that during the coldest week of the study period, i.e., when the indoor-outdoor temperature difference is greatest (that ending January 14, 1927), respiratory illness absenteeism was far below the average for the period as determined by the general trend.

The second coldest week of the study period was that ending March 4, when the outdoor temperature averaged 20° F., 7 degrees colder than the preceding week. Despite this temperature drop, the excess of respiratory illness absenteeism declined to two-thirds that of the previous week.

TABLE VIII

INDOOR-OUTDOOR TEMPERATURE DIFFERENCE, PRECIPITATION AND RESPIRATORY ILLNESS ABSENTEEISM IN 48 ONE- AND TWO-ROOM RURAL SCHOOLS—DECEMBER 6, 1926, TO APRIL 14, 1927

Comparing the data in columns 2 and 3 of Table VIII shows that excessive precipitation (above the mean) is followed, 6 times out of 7, by excessive respiratory illness absenteeism in the following week, the only exception to this rule being the last week of the study. Of the

other 3 weeks to show an excess of respiratory illness absenteeism, 2 follow weeks with excessive precipitation with a lag of 2 weeks. The remaining week to show respiratory illness in excess (0.2 per cent) of the trend line value is that ending February 18, 1927, a week during which the precipitation was practically double that of the mean, the effect on the incidence of respiratory illness showing more promptly than usual.

Although the correlation coefficients involve the magnitude as well as the correspondence in the deviations, they amply support the suggestion from the Syracuse Study that fluctuations in respiratory illness (as reflected in the absenteeism reported due to this cause) are closely associated with precipitation.

SUMMARY OF FINDINGS

1. In these studies, the curves of respiratory illness absenteeism follow the same *general* trend as does the curve of difference between the weekly mean indoor and outdoor temperatures (see Figures I and II).

2. In the 2 mechanically ventilated schools, there appeared to be a high degree of relationship between the variations in the respiratory illness absenteeism and the amount of precipitation with a lag of 2 days. Correlation coefficient $+ 0.84 \pm 0.09$ (see Figure I and Table V).

3. This close relationship between precipitation and respiratory illness did not appear to hold true for the two naturally ventilated schools. Correlation coefficient $+ 0.34 \pm 0.27$ (see Figure I and Table VI).

4. In the one- and two-room rural schools of Cattaraugus County, the variations in respiratory illness absenteeism appeared to be closely associated with precipitation but with the lag of 1 week. Correlation coefficient $+ 0.64 \pm 0.15$ (see Figure II and Table VIII).

5. In none of these three groups does the variation in absence due to respiratory illness appear to be closely associated with changes in the outdoor temperature. The correlation coefficients when the parallel general trends are removed are:

1. For the mechanically ventilated schools (See Figure I and Table V)	-0.34 ± 0.27
2. For the naturally ventilated schools (See Figure I and Table VI)	-0.30 ± 0.28
3. For the rural schools (See Figure II and Table VIII)	-0.15 ± 0.24

CONCLUSIONS

1. The variations in the incidence of acute respiratory diseases in three groups of school pupils during the school year 1926–1927 appear to be more closely associated with variations in precipitation than with variations in outdoor temperature.

2. A possible explanation of this may lie in the following facts:

a. The evaporation of moisture from the shoes and clothing of the pupils is a heat absorbing process—60 b.t.u. of heat (15 kilogram-calories) being required to evaporate each ounce of water.

b. Under normal conditions of classroom occupancy, the heat required to effect this evaporation of moisture is absorbed from the pupil.

c. Unless pupils' heat production is sufficient to compensate for this abnormal heat extraction, they will be chilled either sensibly or insensibly.

3. Just how such chilling is associated with the onset of acute respiratory disease is not clear.

Before-and-After Statistics

WE are frequently confronted with a chart showing, by the heights of two bars, the average death rates from some given cause, for 5 years before and for 5 years after the inauguration of some campaign against the disease in question. If the later 5-year average rate is appreciably lower than the earlier, it is held to be demonstrated that the program undertaken was followed by a decline in mortality from the disease combated. Such *may,* in fact, be the case; but it may not.

Inquire of the person compiling the statistics why he used the death rate over a period of 5 years, and he will reply that it was in order to " smooth out the chance fluctuations " or to " reduce the probable error." Admittedly, a 5-year death rate is less subject to " chance variations " than is the rate for a single year; especially is this true where the population concerned is small.

But it very frequently happens that this process of " smoothing out chance fluctuations " also smooths out all meaning from the data. Let us take the typical instance of Bunkville, a city which has been carrying on a campaign of publicity against typhoid fever since the beginning of the year 1923. After waiting for 5 years, wisely, in order to have sufficient data to evaluate the results of the experiment, the Bunkville Health Department published a graph, which is reproduced here (Figure I), showing that during the 5 years 1918–1922 the average typhoid fever death rate was 14 per 100,000 population; and during the 5 years following, only 11 per 100,000 population—a reduction of over 20 per cent following the inauguration of the publicity campaign.

The present writer has taken the trouble to obtain from Bunkville the statistics for the separate years composing the two 5-year periods. These data are shown in Figure II. It appears from them that the decline in mortality from typhoid took place entirely *before* the beginning of the publicity campaign, and that since the campaign was started there has been a continual increase of the rate.

One can easily demonstrate that if the situation in Bunkville had been different, the average death rate for the second 5-year period in question might have been higher than the first, and yet a very definite reduction might have taken place after the beginning of the campaign. It is also, of course, possible to construct situations in which the two 5-year averages would truthfully portray what had actually happened.

It should be apparent that the essential thing to be measured in evaluating the effects of a campaign against a disease is the change brought about in the *trend* of the mortality or morbidity rate. Thus if it could be shown that as a result of a given campaign a specific death rate which had been rising from year to year was made to fall, or to rise less rapidly, some progress might be claimed. The practical

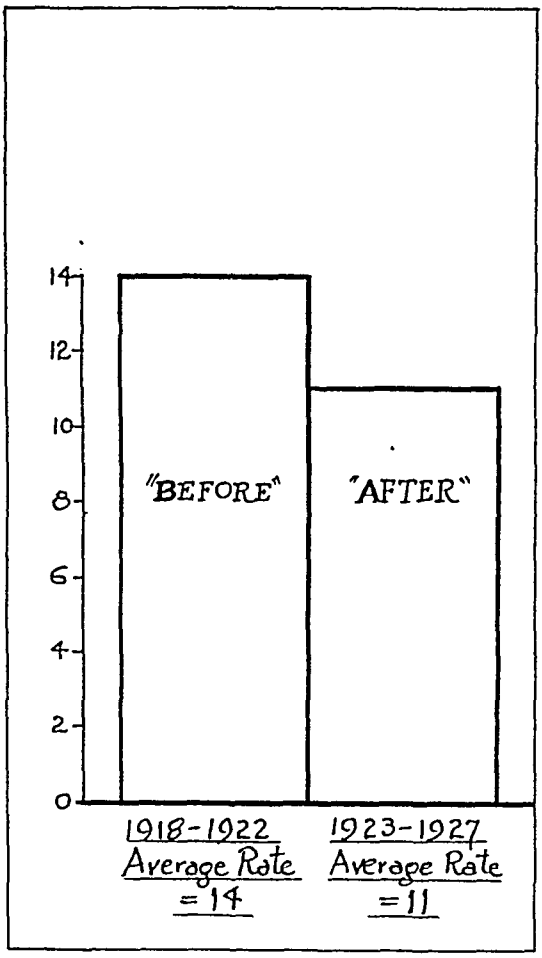

Figure I - The Story as Told by Averages.

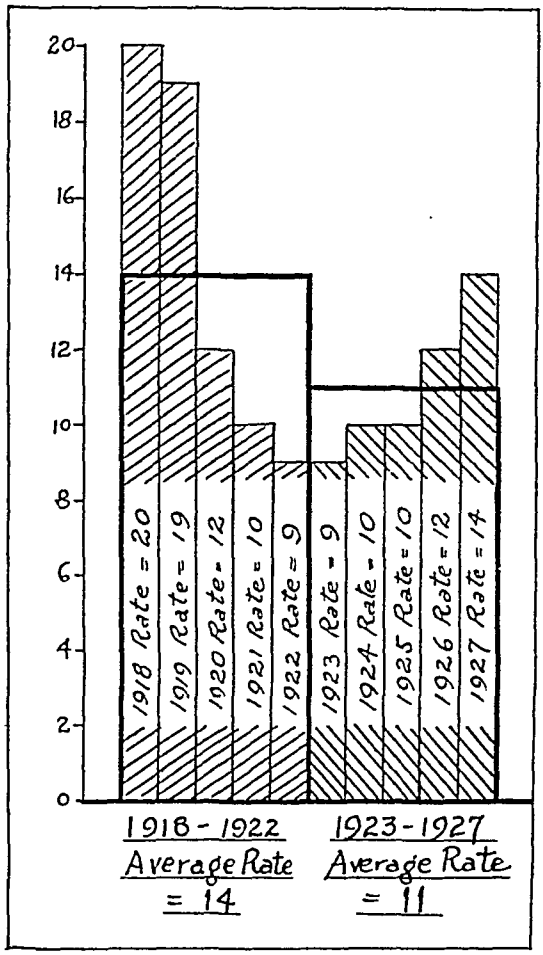

Figure II - What Actually Happened.

objection almost raises itself: But to compute a significant and reliable trend, you generally need more than 5 years' data. True! But the general use of the average death rate for 5 years before and 5 years after some event, however simple and easy of computation, is about as likely to give rise to false conclusions as to true ones. There may be legitimate uses for "before-and-after" averages for popular presentation but before using them they should be carefully examined in the light of the trends within the 5-year periods, in order to be sure that in the particular case it is certain that the true state of affairs will not be misrepresented. In fact, it is questionable whether it would not generally be preferable to show the course of a disease from year to year, even in material destined for the eyes of the "ignorant layman."—Elbridge Sibley, Nashville, Tenn.

The Possible Relationship of Mutual Benefit Associations to the Health of Employes*

H. A. SEYMOUR

Superintendent Employes Service Division, Commonwealth Edison Company, Chicago, Ill.

INSURANCE is the modern man's solution of the problem of how to avoid being wiped out prematurely by one of the hazards of life, instead of opposing them with no more than his individual strength and resources.

The first important point I wish to make is the close connection between financial aid for the average bread winner when disabled, and the time required for his recovery. It is very obvious that privation and worry due thereto delay recovery in cases lasting only a few weeks; but there must be added to that the other risk of premature return to work under the lash of necessity, resulting from lack of aid from a sick benefit association.

It is not alone the loss of income, but frequently the special expense of treatment of the disease or the non-industrial accident causing disability which makes the situation acute. Some physicians charge as low as $1.50 for attention to an ordinary case in their own offices, but this varies up to $3.00, and visits to the patient's home cost from $3.00 to $5.00 each. The cost of nursing service, beyond that available in the ordinary family, is prohibitive to all but those in the wealthy class; so that cases of pneumonia and similar diseases among wage earners are almost invariably removed to a hospital where adequate care can be obtained free or at a smaller cost.

Aside from the aid to recovery, the effect of employes' mutual benefit associations upon the health of their members is strongly preventive of avoidable disablement. That is the second big point. This is brought about by sheer necessity, because in the scheme of dues and benefits the association must plan as closely as possible. The former must be low enough and the latter liberal enough to attract healthy members and keep them. Hence, a very careful and alive

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 19, 1928.

administration is essential; claims must be well proved before being paid; and, further, a critical view of the means employed to aid recovery is insisted upon in the interests of all. This leads directly to visits to the disabled, and inspection of home conditions bearing upon their health. It is common knowledge that no efforts in that direction have been exerted by lodges or friendly societies comparable to those which have been made by industry since the idea of its responsibility for the general welfare of its workers developed after the beginning of the 20th century. In fact in some instances, severe criticism of too stringent measures in that direction has been evoked.

We must recognize and avoid the pitfall of paternalism, especially in some of its obnoxious manifestations. But the fact remains that outside of the employer's interest and activity along those lines, the influence of a closely knit mutual benefit association, organized by and among the workers themselves, makes itself felt in the improvement of conditions both in the home of the worker and on the job.

The association has the great advantage of being in a position to refuse benefits where necessary improvements of that kind at home are wilfully neglected. As a direct result, members and their families become educated along lines vital to the maintenance of health. The requirement of a physician's certificate, periodically during the disability, forces people who would otherwise avoid the expense of medical attention to the detriment of their health, to employ a physician, even in short absences. The association's responsible officers know that long disabilities grow out of short disabilities, unless such a course is pursued. All this works toward the education of all of the employes of the industrial concern, in which the association exists, toward habits of health and adequate attention at the onset of disease.

I do not know of a single employes' mutual benefit association in which the employer is not directly interested to the extent of active participation in some way. In large concerns the medical department is a well established modern necessity from the employer's viewpoint; and the assistance in the development of such a department which the employes' association renders is another direct relationship between the association and the health of all the employes.

Well organized medical departments, and also mutual benefit associations of employes, seem to refer especially to big business; but small institutions can really do something along these lines if they will appoint some executive to study their own situations and work out a suitable plan along the lines of health maintenance, with the dual object of maintaining the best personnel efficiency and aiding in the individual welfare of employes.

In fact, in the ideal situation, the employer takes an authoritative

interest in each disabled employe's case, through the operation of rules governing employer's benefits paid (whether through the association or not) in such a way that the employe is fully aware of such payment. To my mind, that is vastly better than payment of the same annual total by the employer into the treasury of the association—an impersonal transaction. The right method improves morale and the relationship of employer and employe throughout the whole organization.

In summarizing the relationships of the mutual benefit association to the health of employes, it will be well to note certain features which appear to be disadvantageous and state the immediate answer to each.

APPARENT DISADVANTAGES

1. *The tendency toward malingering* is encouraged if benefits are too liberal; and that error should be avoided at the beginning, as it is difficult to change the basis afterward.

The general answer to this problem is that malingering is minimized by close supervision, not merely through lay-visiting, but by insistence upon reliable medical inspection, and due regard to moral hazard with reference to the known character of the disabled employe. A check on this sort of thing is to spot repeaters, and treat as recurrences frequent disabilities due to the same cause, in which case the decreasing scale of benefits removes the moral hazard.

2. *There may be an apparent increase in the sickness disability rate* shortly after a benefit plan has been put into operation among a large group of employes.

I suggest that the answer is, in part at least, that the improved health program brings to light incipient disease which must be met by enforced absence from duty, combined with adequate treatment. There is an increased health consciousness in the group, resulting, first, in the more frequent recognition of cause for absence; but if the whole system is adequate, this merely results in better actual health conditions and improved future risks. There are more complete records of health conditions, and of disability absences by kinds and causes; but I submit that it is better to know the truth than to believe, fatuously, that we were formerly better off because more ignorant.

3. *The likelihood of attracting applicants for employment not robustly healthy* and who, therefore, seek employment in business concerns known to have liberal disability benefit and other welfare plans, has been noticed by writers on the subject of employes' benefit associations.

Of course, the answer to this is careful entrance examinations to prevent the hiring of those obviously unfit, in which an important feature is the use of a proper scale of physical classification, aligned definitely with the job analysis of the concern's work. If that is well done, the entrance examination will prevent the acceptance of applicants for and transfers of employes to positions they are not physically qualified to fill.

This leaves open the subject of nervous instability, which is hard to detect by physical examination; and it must be admitted that many people are hired, especially women, by concerns having large numbers of clerks, among whom some troublesome cases of nervous disability develop.

The answer to that is adequate departmental administration. By that I mean that a department manager should learn early in the history of a case of nervous instability that he has such an employé on his payroll, and he ought to be guided by ordinary business principles to eliminate that employe at a suitable time. This policy should be followed with any employe who is in any way sufficiently abnormal to remain below reasonable efficiency after having been labored with, and after having been given genuine opportunity to improve his record. Objections that may be made to this policy are mostly sentimental, because, had the condition been detectable, the entrance examination would have prevented the employment of that applicant in the first place. The association's officers will argue for the sensible administrative policy and, if possible, see that it prevails because of their direct financial responsibility to the association.

SUMMARY OF ADVANTAGEOUS RELATIONSHIPS OF THE ASSOCIATION TO EMPLOYES' HEALTH

1. *More searching and more frequent physical examinations* of employes than will otherwise be made, both at the time of employment and later on, are induced through the association's policy and operation.

2. *Better attention to hygienic and sanitary conditions* in the employer's premises are procured.

3. *Employes are induced to obtain medical attention promptly in apparently simple sicknesses* instead of relying too much on "home remedies," thus shortening these disabilities and preventing their development into long ones (colds into pneumonia, etc.). Although this is a hard thing to accomplish, the coöperation of the association and the employer in demanding a physician's certificate of disability and of medical attention, if benefits are to be paid for short sickness disabilities, will succeed in this object.

4. *The duration of lengthy sickness disabilities is curtailed* by better medical attention, and because of less worry and privation.

5. *Complete recovery before return to duty* is not only permitted by the alleviation of the financial burdens of disability, but is enforced, the association compelling its members to obtain the medical department's discharge. Frequently the association officers, in coöperation with the industrial management, aid in finding appropriate light work, or part-time work, for those who would otherwise have to remain off duty still longer to avoid a relapse with its attendant evils.

6. *The same advantages of policy operate directly to cut down the death rate* among employes.

7. *Employes whose home living conditions are below par are encouraged to improve them,* and to seek better quarters, if necessary.

8. *The association officers will assist in obtaining adequate treatment more speedily* in lengthy cases requiring institutional care, such as tuberculosis, neurasthenia, etc.; and in obtaining, if necessary, special financial aid required for a change of climate, for example. This results in better recovery, or in enabling the member to settle in another part of the country.

9. *Health records of all employes are more completely kept,* and can be better studied and the needs of each and all understood. This enables general improvement by comparison of sickness experience with other associations throughout the country.

10. *A very definite health program, with the active coöperation of the em-*

ployer, through an adequate medical department, is included in any sound plan establishing a mutual benefit association of employes.

11. *A medical department already established is encouraged to develop its work* to the point of greatest reasonable efficiency by the required coöperation with the employes' mutual benefit association when *it* is established.

12. *The health program is stimulated where it needs it most* by establishing a competitive basis between occupational exposure groups. This can easily be done in large organizations where employes are engaged in widely different kinds of work by organizing the benefit association into sections, by such groups, with reference to disability funds only.

13. *Health-mindedness throughout the whole organization is stimulated, and good health is promoted,* by the publication of various items in the employes' magazine or newspaper illustrating the benefits of membership; and by the publication of association reports and health items prepared by the medical department.

14. *Health insurance helps to create the habits of thrift* in other directions, resulting in improved living conditions among the lower paid classes. Health makes thrift and thrift makes health.

15. In general, every well managed mutual benefit association, by contributing its quota to the health of its community, assists in the general social economic advancement of society. This country's loss of a quarter of a billion dollars annually, due to sickness, is largely a direct loss to productive industry. The more health insurance spreads throughout the nation, the greater our prosperity and the better off we shall all be.

Mobilizing Mutual Benefit Associations for Health*

MAGNUS W. ALEXANDER

President, National Industrial Conference Board, New York, N. Y.

AS originally conceived, industrial medical work was primarily curative rather than preventive. It filled a great need in industry by providing suitable treatment for the injured and sick and also by preventing, through careful treatment and follow-up, aggravation of injuries and prolonged periods of disability. But its object was essentially the repairing of the damage already done. In its advanced form, medical work in industry seeks to eliminate the cause rather than merely to mitigate the consequences of injury and illness; to hunt out and eradicate incipient disease instead of waiting for the disease to develop before attacking it. But the plant physician cannot usually accomplish this unassisted. He comes into contact normally only with those who need his services quickly, and his time is usually so fully occupied with the injured and sick that he has scant opportunity fully to develop the preventive possibilities of his position.

In establishments which have no plant physician, even on a part-time basis, there is all the greater need for some agency to assume the initiative in sickness prevention and in an effective campaign for health preservation. Fortunately, in many plants an agency appears ready at hand which can easily be adapted to just such a purpose; in others it can readily be installed. The average employe quickly responds to a proper appeal for his coöperative attitude, and in order to make and sustain an effective appeal—made more difficult by the increasing dimensions of individual industrial plants—and to secure coöperative harmony in the conduct of business enterprise, organized programs of industrial relations activities have been developed which have successfully passed through the stages of experimentation until in many establishments they have now become an integral part of administrative procedure.

THE MUTUAL BENEFIT ASSOCIATION AS AN AGENCY FOR HEALTH WORK

Among industrial relations activities, one stands out as being rather unique because it is composed of, and usually officered and operated by, the employes themselves. Mutual benefit associations, as the

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

name implies, are organized for the mutual benefit of the plant employes who have banded together in such associations and, however much or little attention and financial assistance management may devote to them, they are essentially the employes' own organization. A study of mutual benefit associations indicates that the main thought among workers in forming them, and among management in assisting their formation and conduct, has been the desire to establish a systematic coöperative means of securing for their members some measure of protection against loss due to accident, illness or death, in addition to the protection afforded by workmen's compensation laws or other means.

Broadly considered, the mutual benefit association is a mutual insurance venture in which the dues of the members and the contributions by the employer, where made, correspond to the premiums paid by policy holders to regular insurance companies, and the relief benefits of the former correspond to the insurance payments of the latter. With the recent growth of group life, and sickness and accident insurance, some of the mutual benefit associations have transferred their insurance risks to regular insurance companies, thus relieving themselves of their function of offering sickness, accident and death benefits to their members through coöperative methods.

Whether this procedure is in the interest of the employes composing the mutual benefit associations and of the associations themselves is a moot question. No doubt, it increases the certainty of benefit payments, since in the case of an insurance company, premium payments and benefit payments have a sound actuarial relationship, a fact which is not always true of mutual benefit associations.

As a matter of fact, I know of no case where a member of a mutual benefit association suffered a loss of benefits due him, for either the association fund was adequate to make the payment or the employing company made up the deficiency if it occurred. On the other hand, by transferring its insurance service to a regular insurance carrier, the mutual benefit association ceases to function for the very purpose for which it was organized, and replaces a strongly personal relationship among its members, especially in times of individual distress, by a more or less impersonal commercial proposition. Moreover, there is a question whether in the long run the mutual benefit association would not prove less expensive to its members than a regular insurance carrier, because usually the employing company, rather than the mutual benefit association, assumes the cost of administrative expense, and because experience has shown disability and death benefit requirements to be much more infrequent than actuarially determined

insurance payments are designed to provide. It is also reasonable to assume less malingering among the members of a mutual benefit association carrying its own insurance risks than among the same group of people insured by commercial insurance carriers. As already stated, this whole question, largely because of its newness, is still a debatable issue, and I wish here only to point out that, while on the one side there may be a gain in security and amount of benefit payments, there may also be on the other side considerable loss of psychological values.

But whether or not a mutual benefit association transfers its insurance risks to an insurance carrier, a new and useful field of activity is opening for these associations. Not only can a mutual benefit association be instrumental in promoting and coördinating the social and recreational activities of the employes in an establishment, and in these and similar ways serve as a valuable point of contact between management and the employes collectively, but the benefit association, organized and managed by and possessing the confidence of its members, is ideally equipped to sponsor a movement and carry through an effective program in the interest of the health of its members and their families.

REQUIREMENTS FOR EFFECTIVE HEALTH WORK

The basis of preventive health work is the physical examination through which physical defect and incipient disease can be ascertained and subjected to appropriate curative procedure. In this respect, mutual benefit association requirements for admission and maintenance of membership are far below what they could be. In a study of 382 of these associations, the National Industrial Conference Board found that the basis of membership in 58 was merely a statement by the applicant that he was in good health, while in 86 associations membership eligibility was dependent upon the results of a physical examination made by the employe's physician, a physician designated by the association, or the regular plant physician. Only 3 associations, or somewhat less than 1 per cent, provided for periodic physical reexamination.

Moreover, those associations which look to insurance carriers for payment of benefits to their members under a group insurance plan do not now require a physical examination for membership eligibility, since the original purpose of such examination—to limit the association's financial liability by excluding those likely to cause a severe drain on the treasury—no longer prevails, and under group insurance no individual physical examination is demanded.

The main purpose of the physical test in industry is to determine

the worker's fitness for a particular task, as well as to discover the more obvious symptoms of disease which may make him susceptible to accident and result in high benefit cost, or which may affect the health and safety of other employes in the plant. From the standpoint of the mutual benefit association, however, as already stated, the purpose of the physical examination, where required, is to limit the financial responsibility of the association.

In contemplating this issue, two questions arise: First, should all employes in a plant be required to join the mutual benefit association in that plant as a condition of securing and maintaining employment? and, second, should all members of the mutual benefit association be required to undergo a physical examination and a periodic reëxamination as a *sine qua non* for securing and maintaining membership?

Valid arguments can be presented on both sides of these questions. My own experience and studies lead me to the observation that it would seem unwise at the present time to introduce the feature of compulsion in either of the two cases. While it would seem desirable that at least in each industrial plant of larger size, perhaps generally in all plants in which 250 or more wage earners are regularly employed, there be a mutual benefit association, it would also seem the part of wisdom not to force the employes to join an association to which they would be compelled to make regular financial contributions, but rather to make the mutual benefit association so effective and helpful in its economical operation that at least the great majority of the employes would voluntarily join. When this much is accomplished, these employe members may then properly ask the management to enforce membership in the benefit association for all plant employes with more than a month's employment duration. The latter provision would be necessary in order to exclude casual workers.

The management could then, in turn, issue a rule to the effect that upon the request of the mutual benefit association in the plant it would in future require all new employes to join the association and abide by its rules and regulations. I know that such a scheme is in successful operation in several industrial plants. It is obviously desirable to bring all employes in a plant into the mutual benefit association, for its benevolent influence would automatically become available to all employes and the management could more appropriately utilize the association as a means of contact.

I feel that physical examination and particularly physical reëxamination as a basis of membership in a mutual benefit association should not be made compulsory at the present time, but that the association should through its educational campaign, and in close coöperation with

the management and the plant medical department, where one exists, encourage its members, in their own interest and that of their fellow workers, to subject themselves to a physical test. Such persistent educational effort, if intelligently carried on, would gradually overcome the natural reluctance of the association members to avail themselves of the benefits of a physical examination, while it should also offer an added incentive to voluntary membership in the benefit association.

If my reasoning is sound, it follows that by tactful and intelligent procedure the desired end—the inclusiveness of mutual benefit association membership in a plant and of physical examination and reexamination of all its members—will in time be accomplished without creating the opposition, with its unfavorable reactions upon the employment relation and even upon the conduct of the enterprise, that might otherwise develop.

The mere requirement of initial physical examination will place upon the mutual benefit association a considerable amount of clerical and follow-up work, and this will be many times multiplied by any enforcement of periodic physical reëxamination. Whether the mutual benefit association should develop the required clerical service, with resultant increase in the expense of operation, and change the character of the association from one of voluntary to one of paid assistants, is also a question worthy of very careful consideration.

The mutual benefit association should first of all devote its efforts toward educating and encouraging its members and other plant employes to join in an effective campaign for good health through personal hygienic and sensible living, prompt attention by competent physicians or nurses to incipient disease and injuries, proper initial physical examination and check-up reëxamination, and through other means that will lead to the same end. Moreover, the mutual benefit association should coöperate closely with the plant medical department, where such is in operation, and in conjunction with the plant physician select local physicians in harmony with its program whom it could recommend to its members for physical examinations and medical treatment. It should prepare and distribute to its members suitable health literature and arrange lectures and talks on the subject; should by other coöperative means strive to overcome the natural inertia of most people to take proper physical care of themselves; and seek to make each member an active health worker for himself, his fellow workers and his family. Where no plant physician is available, the same general procedure should be followed in coöperation

with a carefully selected local physician or a group of physicians who would be known as the association's physicians.

It would seem obvious that in a plant where a physician is regularly on duty, either for full-time or part-time service, he should make the physical examinations at the expense of the employing company, especially since in many plants, with organized medical service of larger or smaller scope, applicants accepted for employment must already have satisfactorily passed a physical test. It is becoming increasingly recognized that the employer has a right to demand such initial physical examination, in the interest of the new employe, the protection of his fellow employes, and also in the interest of the employer. The tact with which employers and their plant physicians have handled this matter has practically completely overcome the earlier antagonism. Compelling employes in service to subject themselves to periodic physical reëxamination may create a new feeling of opposition, especially if a physician engaged by the employer is to make the physical test, because of the fear of the employe that the detection of a physical defect or incipient disease would throw him out of employment. Even if the employe member of a mutual benefit association were allowed to choose another than the plant physician for his physical reëxamination, the mutual benefit association should require that the choice of the examining physician be made from a list of physicians approved by the association and that the examination be in accordance with an approved plan; otherwise the physical examination might in many cases become a mere sham. In any event, the management of a plant should proceed with due caution and tact, in order to remove all basis for fear on the part of the employes that the physical test may tend to deprive them of employment rather than to improve their physical condition. With an atmosphere of confidence thus created, members of a mutual benefit association would readily turn to the plant physician for physical examination without cost to themselves, or to a physician approved by the mutual benefit association, whose services are available at a reasonable rate.

The physical reëxamination of an employe should be different from the examination of an applicant for employment; and by making the former essentially for the purpose of applying such curative measures as will enable the employe to continue at work, much will be gained in removing the opposition to periodic examinations and in making employes seek medical assistance which will prolong their life of productive usefulness.

Experience has shown that diseases which cause the greatest amount of loss of productive time are mostly preventable. A study

conducted by the U. S. Public Health Service, based upon reports from mutual benefit associations covering 114,065 industrial workers employed in different industries in 1924, shows that 10,948 disability cases among the members of those associations resulted in lost work time of 8 days or more. The leading causes of such disability were influenza and grippe, these accounting for 18 per cent of the 10,948 sickness claims. The report states that during recent years no other diseases have been so disastrous from the standpoint of interrupted production, wages lost and cost to mutual benefit associations. For the 5-year period ending December 31, 1924, the U. S. Public Health Service found that the frequency rate of these diseases was 6.6 times that of the epidemic, endemic and infectious diseases against which health work is so largely directed. Compilation of the annual incidence rates for different diseases in disease groups for this 5-year period reveals that respiratory diseases, including influenza and grippe, pulmonary tuberculosis and diseases of the pharynx, accounted for 47 per cent of all the sickness cases. These figures indicate what could be accomplished through the practice of preventive measures which so strongly influence the incidence of these diseases.

CONSTRUCTIVE POSSIBILITIES OF MUTUAL BENEFIT ASSOCIATIONS

If the mutual benefit association is to fulfil its possibilities as a health agency, certain changes must be made in its point of view and in its operation. First of all, it must turn from an attitude of payment for disability or death to an outlook and effort for their prevention or postponement. It must realize that, while assuring its members relief when they are disabled, it will be performing a vastly greater service by preventing the need for such relief. It must recognize that, in promoting the health of its members, it is serving their best individual interests, and that the general improvement of health in the plant will also reduce benefit claims on the association and, consequently, enable individual benefits to be increased or individual membership dues to be decreased. It should encourage adequate initial physical examination and periodic reëxamination as the basis for effective prevention of disease and for conservation of health, and to this end coöperate in every practical way with the medical department of the plant, if there is one, or in connection with the plant management assume responsibility for making competent medical attention and consultation service available to its members at reasonable expense to them. It should, furthermore, coöperate in the efforts for safety of work shops and work operations toward a reduction of accidents, since disease is often greatly aggravated by the condition of the

body following accidents. In stimulating its members to the observation of practical and simple rules of health and hygiene, it should also induce them to carry this work home to all the members of the family. In particular, it should emphasize the importance of developing in the children habits that are conducive to good health in order that they may later on be enabled to undertake life's work without physical handicaps.

But even beyond the confines of the individual plants, mutual benefit associations could properly coöperate with local organizations, like chambers of commerce, and with other mutual benefit associations for the purpose of stimulating community health work and in order to have a skeleton machinery at hand which can readily function in case of a serious epidemic or a catastrophe. It may even prove advisable, as time goes on, to bring the mutual benefit associations in various industries or communities or states, or eventually in a nation-wide way, into close relationship for the purpose of making the work of the individual associations more effective and extending the joint beneficial influence as far as possible into all community life.

It goes without saying that the greatest care must be exercised by mutual benefit associations, by industrial management and in all cooperative relations here suggested, to avoid any appearance of paternalism or commercial exploitation.

DISCUSSION

Meyer Bloomfield, New York, N. Y.—Most of the mutual benefit associations were formed before the war and are stagnant today. Most of them make no mention of health in their inquiries or records. They are merely substitutes for "passing the hat" when someone dies. It is a Victorian age in which they exist. Mr. Seymour's presentations are of the big plants and large groups, but the stagnation of most of these associations is really alarming. Turning these matters over to insurance companies really does impersonalize them and it causes their value and purpose to be lost sight of. However, the insurance company scheme may be better in many situations. There are no statistics to support either side so far as I know at present. We should ask the mutual benefit association what it exists for and what dividends result from its existence in regard to health and to the prevention of disease. If you ask the foreman what to do with a man found asleep on the job he would say "fire him," but the mutual benefit association ought to inquire why he was asleep. Oftentimes the management needs a shaking up. A few months ago Mr. Hunt and others started an organization to overhaul the mutual benefit associations and we may expect results. The health responsibilities of these associations have great possibilities if developed correctly.

E. B. Hunt, Pennsylvania Railroad, Philadelphia, Pa.—Let us not permit the mutual benefit association to dry up by turning it over to an insurance company. It loses its interest. The Pennsylvania Railroad Association is a great factor in harmonious labor relations. It is now 42 years old. Its benefits and other ac-

tivities have often been increased and greatly extended. Back of everything is health. Only certain employes are compelled to take physical examinations. Last year there were 48,000 such examinations. These are required once if a person is 40 years of age or above and every year for certain persons who are 42 years of age or over. Certain objections may have existed at first but have long since disappeared. The whole procedure is welcomed by the labor organizations, whose members support it in the interest of public safety as well as the promotion of their health and well-being.

Volney S. Cheney, M.D., Armour & Company, Chicago, Ill.—We have no mutual benefit association at Armour & Company although I can see where such might possibly help. However, I believe that these matters are outside of the plant management. They are best conducted by outside agencies with certain cooperation from the plant. Let the plant see to bettering working conditions in the plant. The tendency is now for the plant to drop outside welfare work. We used to do it. We have dropped it gradually during the past 7 years. The results were good but the moral obligation was bad. Our business is meat packing first, and the health of our employes second. Our product is made up of the ability and good health of each worker. It is up to each worker to supply these. We cancel contracts if goods are not up to the requirements. We should do the same in hiring and keeping a worker. He, and not the industry, must furnish health, so far as his personal liability is concerned. The natural inertia in these matters does really exist, but the worker must expect to look after himself or lose his job. The mutual benefit association's object should be continuous and not just for certain times or things. We have the group insurance plan and thus far all has gone well. The insurance company furnishes the nursing service and coöperates with our plant medical service. The medical department should be fraternal and not paternal. Let outside agencies be paternal and do not expect such an attitude from an industrial medical department.

Eugene L. Fisk, M.D., Life Extension Institute, New York, N. Y.—A chief antidote to sickness is obtaining the individual's interest in himself. Dr. Cheney's line of demarkation is rather too sharp. There is a universality of interest; for example, if the employe is malingering, the employer is interested. I do not believe the employer can dismiss his interest in the health of each of the individual employes.

Francis D. Patterson, M.D., West Philadelphia, Pa.—I am surprised at Dr. Cheney's remark that a man who does not maintain his health should leave the industry. We are our brothers' keepers. Most of our employes do not know how to keep their health. Often they are too ignorant to know what to do and how to do it. Hence, the employer must assume certain obligations when he employs them if he is to gain the desired end in his own business. It is a folly to have a mutual benefit association and not physical examinations, including the repeating of them. It is a fool's paradise to live in ignorant bliss of disease. I recall that 21 years ago Samuel P. Gompers said that physical examinations had for their chief purpose the "firing" of men, but our answer was that no epileptics, heart disease cases, etc., could be employed or be continued to be employed on railroads, on cranes, etc. The mutual benefit association has a big opportunity.

Wade Wright, M.D., Metropolitan Life Insurance Co., New York, N. Y.—The wise employer, even as an expedient, must recognize the health responsibility he has for his employes. The mutual benefit association is a baby insurance company and, as such, is unsound (you all know that I am an insurance company man). It

is like the baby pop-stand compared with the luxurious catering establishment. In the former, mother finances the scheme. The business of an insurance company is simply to distribute cost in a sound manner. Most mutual benefit associations are very unsound and inadequate. The insurance company requires that malingering would have to be supported by a physician's certificate, and we take care to appoint honest doctors. Where health benefits are provided, they are to help prolong physical activities rather than to prolong life. The worker needs help for financial support while sick, for diagnostic facilities and associated things, and here lies the field for the mutual benefit association rather than dabbling with insurance. Through a good insurance company an employe can be put in the best hospital and receive the best facilities and care for not over $10 per capita per year, where the cost to a "white-collar" man, acting singly, would amount to $1,000. If such an average "white-collar" man were a saver, such a bill would take him 100 years to pay. If he belongs to a reliable insurance company he may get the same care for $10 a year. Our group insurance requires no physical examinations, but this is because insurance has nothing to do with physical examinations; such belong to another category than insurance.

George H. Wood, M.D., Frederick Stearns & Co., Detroit, Mich.—Dr. Cheney should have been a lawyer in Franklin's time. I am sure that compensation insurance is not in accordance with common law since primarily the worker assumed all risks. I think Dr. Cheney's reasons are logical, but we must do this so-called paternal work. Why? The average employe does not have sufficient income, and hence our efforts to help him in times of distress are really substitutes for low wages, which substitutes, however, are spent in a wise way.

Surgeon General Hugh S. Cumming, U. S. Public Health Service, Washington, D. C.—I am certain that Dr. Cheney's position and Dr. Wood's "fellow servant" ideas have quite completely disappeared in America's industrial relations.

Meyer Bloomfield—I am a lawyer and I must defend my profession. The law has learned something in a century. It is progressive and not continually primitive as many think. It is true that law learns slowly but in a century it has discarded the "fellow servant" and the "assumption of risk" ideas and many equally as bad.

Eugene L. Fisk, M.D.—It seems a paradox that what a man continually preaches he is often accused of never mentioning: I have repeated and repeated that the purpose of the Life Extension Institute is to extend the usefulness of life and not merely life itself.

Volney S. Cheney, M.D.—I want to explain my position more clearly. We get tired telling people what to do and not having them do it. We must resort to compulsion. As a matter of fact, we advance no key-man in our organization without a physical examination, but we are stressing that each man owes most to himself.

Bacteriophage From a Public Health Standpoint*

N. W. LARKUM, PH. D.

Bureau of Laboratories, Michigan Department of Health, Lansing, Mich.

DESPITE the enthusiasm which has been evidenced by most investigators who have undertaken therapeutic work with bacteriophage, the use of this principle has not spread and a study of the literature of the past two years indicates a decrease rather than an increase in its use. In seeking the cause for this decline, it is necessary to present the fundamental conceptions upon which bacteriophage therapy depends.

A substance capable, even in extremely small quantities, of killing and of dissolving the bacteria with which it comes into contact and which at the same time is harmless to animal tissues, should have an immediate application to sterilization of body cavities in which bacteria are present. Unfortunately, however, although a principle might be obtained capable of killing and dissolving, let us say, *B. coli,* its action is generally confined to the single strain of *B. coli* in question. A bacteriophage race which will attack one strain of this organism will not necessarily attack another strain. Furthermore, although dissolution can be demonstrated without difficulty, prolonged incubation of the dissolved culture results in the appearance of new growth. This growth, while still *B. coli,* will not be dissolved by the bacteriophage which at first attacked it. Such a culture is termed resistant and, although a new race of bacteriophage may dissolve it, the discovery of such a race is not always an easy matter. It has been further shown that these resistant cultures are more virulent than their susceptible ancestors or precursors. By using bacteriophage races of high virulence, however, the production of secondary cultures may be reduced, if not eliminated.

This outline is essentially the foundation upon which earlier experimenters based their hopes for bacteriophage therapy and, indeed, it is sufficiently alluring at the present time, for it contains within it the explanation for the successes as well as for the failures attending bacteriophage therapy to date. It does not require much exercise of the imagination to attribute to a weak race of bacteriophage most if

* Read before the Laboratory Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

not all of the failures in therapy. When we have reviewed the results obtained by workers using this conception as their foundation for therapeutic procedures it will, I think, be apparent that the results obtained illustrate the fundamental soundness of the theory. It should then be as attractive today as it was five years ago. If it is not, the reason can only be that the results of practice have failed to justify the hopes based on the theory. That such is not the case, but rather that unfair, biased interpretations have been derived from a failure to consider all of the evidence will become apparent as we proceed.

The infections to the cure of which bacteriophage has been applied are now rather numerous. They include bacillary dysentery, typhoid fever, cystitis and pyelitis, plague and cholera, gonorrhea, and various infections due to staphylococci and streptococci. The enteric diseases, infections of the urinary tract, and staphylococcus infections in general have received by far the most attention.

In so far as dysenteries are concerned, it must be admitted that a mere statistical study of the results reported would justify a rejection of the principle as a possible valuable agent in treatment. Critical analysis of the reports however would inject an element of doubt into this conclusion, for it would be seen that results obtained with dysenteries caused by the Shiga bacillus were better than were those where the Flexner or other strains were concerned. Furthermore, nationality of the investigators has played an important rôle in the results reported. The German investigators have obtained negative results, the French positive, while the British and North Americans have been more or less neutral. From South America, however, comes the greatest support for the principle. Although actual figures are not available, Da Costa Cruz reports very favorable results attending the widespread use of Shiga bacteriophage.

Treatment of typhoid and paratyphoid fevers gives similar conflicting results depending again upon the nationality of the users. About all that can be gained from a study of the literature is the impression that, should the reader be so unfortunate as to contract the disease, his first request would be for a potent race of bacteriophage.

In urinary infections the picture is more distinct, and the results are more clear cut. Whatever criticisms one may have as to the convincing nature of the results, it must be admitted that of those who have administered the treatment none has given an unfavorable report. Although exact figures are not available it may be estimated that several hundred treatments for urinary infections have been given with universally satisfactory results. The same remarks apply to treatment of staphylococcus infections of all types. The unanimity of the conclusions, even deducting for optimism, is striking.

With respect to the remainder of the infections mentioned above, even the most ardent advocate of bacteriophage must withhold conclusions. At most, they but add to the interest in the question.

If, in addition to the above information, one is conversant with the work now being carried on and as yet unpublished, he is likely to become convinced that the bacteriophage has inherent possibilities as a therapeutic agent. Such workers as Cowie, Rice, Caldwell, Dutton and others, although not so well known perhaps as Davison (the only worker in this country to publish an unfavorable report as a result of personal experience in bacteriophage therapy), have a great deal of work to their credit, some of which has been published in journals with limited circulation, but much of which has remained unpublished.

But I do not advocate bacteriophage for therapeutic and prophylactic purposes because I have read much about it, nor yet because I happen to know about work that has not been published. I believe in this principle because of my own experience in its use during a period of five years. Most recently I have been concerned with the application of staphylococcus bacteriophage to the treatment of furunculosis, acne, and osteomyelitis. Already a report has been published of the treatment of 66 cases of furunculosis with striking results. These have been continued, until today records are available of more than 300 cases of furunculosis, more than 50 cases of acne, 8 or 10 cases of styes, and several cases of osteomyelitis.

There is not space, nor am I prepared to give concrete data on these treatments. They will appear in due season in the literature. But the results are sufficiently striking to cause reputable physicians, men of years of experience in practice, men usually cautious in their reactions to therapeutic agents, in submitting their reports to use such adjectives as "wonderful," "striking," "remarkable." This does not warrant the wholesale distribution of bacteriophage or the sale of the agent as a new specific; I would be the last to recommend such a thing. That it does warrant continued investigation I insist.

Before passing from this question of my personal experience with staphylococcus bacteriophage, I would like to inject a consideration of the fundamental conceptions upon which this work is based. Unlike the earlier work the bases for which I have already described, these treatments were designed to bring into operation two observations made long after the discovery of the bacteriophage. I refer to the antigenic action of bacteriophage-lysed cultures, and to the antivirus of Besredka. With respect to the first, it has been shown by many investigators, notably d'Herelle, G. H. Smith, Nelson, and Arnold, that bacteriophage increases the opsonic index to an unbelievable degree

and that filtrates of bacteriophage-lysed cultures can produce all of the antibodies produced by the same cultures when killed by heat and to approximately the same degree. It is necessary, however, in stating this fact to bear in mind that in none of these experiments has the bacteriophage been separated from the bacterial proteins resulting from its action. Whether the bacteriophage or the proteins are responsible for the reactions it is impossible to say.

So far as the antivirus is concerned, it must be pointed out that here we are dealing with two factors, a product and a method. The product is a filtrate of old bacterial cultures; the method is that of local immunization; that is, the filtrates are applied directly to the tissue infected. Bacteriophage is likewise a filtrate. To what extent it is identical with antivirus is as yet undetermined, but the method of local immunization may be used with the bacteriophage as well as with antivirus.

Thus it has come about that instead of believing, as did the earlier workers, that it was necessary to have a bacteriophage capable of lysing *in vitro* the organism with which a particular patient was infected before successful therapy could be accomplished, and feeling that actual contact of bacteriophage and organism should occur in the tissue or cavity infected, I have felt that all that was necessary was to have staphylococcus protein as produced by bacteriophage inoculated into the patient, or, according to the type of infection, applied locally.

This changed conception as to the possible rôle of the bacteriophage in treatment has led to a consideration of its use in prophylaxis. Although, apparently, public health officials and workers are irrevocably committed to the use of so-called typhoid vaccines, it is debatable whether their trust is well placed. I think there will be no opposition to the statement that no biologic product for the promotion of immunity is entirely satisfactory or beyond improvement. If this is the case, nothing more is needed to justify an investigation of a substitute for the well known vaccine, while the road along which such an investigation should proceed has been suggested in the consideration of the basis for the therapeutic work with staphylococcus phage.

Lysed bacterial cultures are antigenic. Because of this fact I undertook a study of the results of human inoculations with filtrates of lysed cultures of *B. typhosus, B. paratyphosus A,* and *B. paratyphosus B,* and immediately learned that doses of bacteriophage as great as 4 c.c. could be given subcutaneously or intramuscularly without more reaction than would accompany the administration of a similar amount of saline, that is, a slightly sore arm. This is the first respect in which bacteriophage-lysed cultures differ from the usual vaccine. In about 200 injections I have not had a single reaction.

Comparative studies of response to inoculations with vaccine and with the bacteriophage lysates have been carried on for many months with the following results:

The agglutinin production following inoculation with bacteriophage lysates is practically identical with that following the vaccine inoculations although it is more rapid. Bactericidal action of the blood of those inoculated with lysate a month previous was consistently higher than that produced by the vaccine. One month after inoculation the opsonic index of the serum of those receiving the lysate was about double that of the individuals who received vaccine. The number of inoculations involved is now more than 200, about equally divided between lysate and vaccine. Much remains to be done and much has been done that I prefer not to mention at this time. Certainly the duration of this immunity, if such it may be called, is most significant.

No experiment that depends upon serological response as a determination of immunological value of an agent is adequate. Especially is this true of the bacteriophage. Such evidence as we have points to the fact that the degree of immunity resulting from use of bacteriophage is out of all proportion to the antibody response demonstrable. The bacteriophage possesses several characteristics which, could the immunity resulting from its use be shown to be even equal to that produced by the vaccine, justify, indeed demand, its substitution for that agent. These are: Freedom from reactions, a factor of inestimable value when it is considered that one of the chief objections to inoculation is the discomfort amounting to disability in some cases; the ease and cheapness of production; the variety of antigens which may be included; and the availability of the prophylactic agent as a therapeutic agent in case of epidemics.

Besides the advantage of lessening the objection to typhoid inoculations, the fact that bacteriophage lysates produce no reactions has another advantage. It is possible to give much larger doses, a fact which might serve to reduce the number of injections required.

As to the ease and cheapness of production, it is only necessary to state the methods used in these experiments to indicate possibilities:

To a gallon bottle of peptone water, three slants each of typhoid, para A and para B are added, and about 10 c.c. of bacteriophage. After 24 hours' incubation the broth is clear and is filtered to prevent the development of secondary cultures. The flask is then re-inoculated. This is repeated a third time. The amount of bacterial protein contained is thus very many times that found in a vaccine containing 2 billion organisms per c.c., while the only labor involved is the filtration—not an hour's job with a Seitz filter—and this may be omitted.

One question which may be anticipated at this point concerns the use of preservative. None has been used in the bacteriophage utilized for these experiments, and it is preferable that none be used since it destroys the possibility of using the bacteriophage for treatment. Phenol, moreover, decreases the potency of the bacteriophage without

entirely destroying it. It is possible that some other prevention for bacterial contamination may be employed.

Since the amount of bacterial protein that may be accumulated in these filtrates without causing reactions when they are injected is not narrowly limited, it is obvious that, providing the bacteriophage used will give lysis, several bacterial species might be included in the lysate. Shiga dysentery lysate, in particular, could be employed since filtrates of this organism when lysed are non-toxic. Enteritidis, indeed all of the salmonella group, might be added. The bacteriophage used is lytic for all of these organisms. Thus a single injection or at most three injections might serve to immunize against all enteric infections.

I come now to a justification of my title, "Bacteriophage from a Public Health Standpoint." To one who has given the least thought to this problem it appears that in bacteriophage we have a potential therapeutic and prophylactic agent for the control of epidemics—for the control of infectious disease. Have we not likewise a duty? The health departments of states and cities were early advocates of all of the better known and more widely used biological products; if they doubted the value of the principle, they at least gave it a fair trial. Why not then bacteriophage? I venture to state that as much justification now exists for the use of bacteriophage by the public health departments as ever existed for the use of scarlet fever toxin or antitoxin. The difference is this, that we have no bacteriophage for measles, for poliomyelitis or for encephalitis. In brief, for those diseases in the control of which we have no satisfactory or readily used cure or preventive, no bacteriophage has been developed. But does this excuse us from improving upon the agents now in use? Because furunculosis is not contagious is it less a function of the health department to promote the development of a measure which may relieve considerable suffering? Moreover, until the principle that bacteriophage or the antigens that bacteriophage makes available is accepted as applicable to the cure or prevention of any given infection there is little incentive to develop new bacteriophage. Why strive to develop a lytic principle which may be turned to the treatment of streptococcus infections if we are unable to secure a hearing for the staphylococcus bacteriophage? I only plead for a fair trial for a principle which under most difficult circumstances has more than demonstrated its potentialities. Make no hastily considered changes; put no product into general circulation; but make available the great resources at your command for the trial of bacteriophage.

Vital Statistics and the Measurement of Health Progress Fargo, N. D.

ROBERT E. CHADDOCK, PH. D., FELLOW A. P. H. A., EMMA A. WINSLOW, PH. D., and CAROLYN A. BOUDO

Research Consultant, Director of Research, and Statistician, The Commonwealth Fund Child Health Program, New York, N. Y.

PUBLIC health services in Fargo, N. D., underwent rapid expansion in 1923 following the establishment of the first of the Commonwealth Fund child health demonstrations. A full-time health officer, the first in any North Dakota community, replaced the part-time health officer of the pre-demonstration period. More public health nurses were employed, as well as a pediatrician, a health educator and (in 1927) a public health dentist.

As a means of discovering if possible the effect on the status of community health from this increased volume of public health activity, much attention has been given in Fargo to the study of vital statistics, growth changes in children, and other data which seemed likely to yield definite information as to the nature and extent of health improvement.*

In the use of vital statistics in the measurement of health progress desirable procedures in analysis and interpretation proved exceedingly difficult to formulate. Many local births and deaths are of non-residents, and whether or not they should be included in measurement tabulations was a matter of much importance. In a city with but 26,000 population, births and deaths each year are few, and variations in yearly rates have little significance as an index of health change. Complete and accurate registration extends back only a few years before the establishment of the demonstration, and as yet trends in local vital statistics can be determined with reference to only a very short period of time.

Procedures were finally worked out which seemed adapted to the analysis for measurement purposes of the type of vital statistics at

* For detailed description of demonstration organization and accomplishments, see Fargo Final Report—Part I, Five Years in Fargo; Part II, Public Health Work in Fargo; An Appraisal by W. F. Walker, D.P.H.; Part III, Serving the Child in Fargo. Copies may be secured on application to the Commonwealth Fund Division of Publications, 578 Madison Avenue, New York, N. Y.

present available. The methods used in this phase of the Fargo measurement program are described in considerable detail in order to serve the needs of public health administrators and others facing similar problems of analysis elsewhere. Certain of the more important findings from these studies are also included as illustrations of what it proved possible to learn from the analysis of vital statistics concerning recent changes in local health conditions.

Under the Vital Statistics Law in North Dakota the responsibility for the local registration of births and deaths rests with the city auditor or the village or township clerk, but in Fargo beginning with the demonstration period duplicate copies of certificates were kept on file in the office of the City Health Department. All certificates were carefully checked and physicians queried as to doubtful entries. Tabulations for monthly and annual reports were made routinely under the direction of the demonstration statistician, and these were supplemented by special studies when necessary, such as in the detailed study of infant mortality.

While the city was admitted to the U. S. Death Registration Area in the year 1916, its inclusion in the U. S. Birth Registration Area was not possible until 1924 when the whole state of North Dakota was able to qualify for admission to both the birth and death registration areas. Study of local standards in reporting, however, showed that beginning with 1920 records of both births and deaths were sufficiently complete to justify dependence upon them for measurement purposes, and tabulations similar to those for the demonstration years have been made from data in the birth and death certificates on file in the office of the State Department of Health.

Fargo is the hospital center for a large surrounding area in North Dakota and Minnesota. Within the city also are located several small institutions for unmarried mothers and dependent children where care is given to both residents and non-residents. It is therefore not surprising that the number of non-resident births and deaths during the years covered in this study has been nearly the same as resident, as shown in Table I. This proportion has fluctuated somewhat from year to year so that total rates including non-residents have not been affected uniformly by the factor of non-residence.

Total death rates and birth rates, as illustrated in Figure I, are quite different if non-residents are included or excluded. Both the birth rates and death rates when calculated with reference to residents only are about the same as recent rates for North Dakota and Minnesota. If non-residents are included, they become abnormally high.

Local observation indicates that relatively few births and deaths

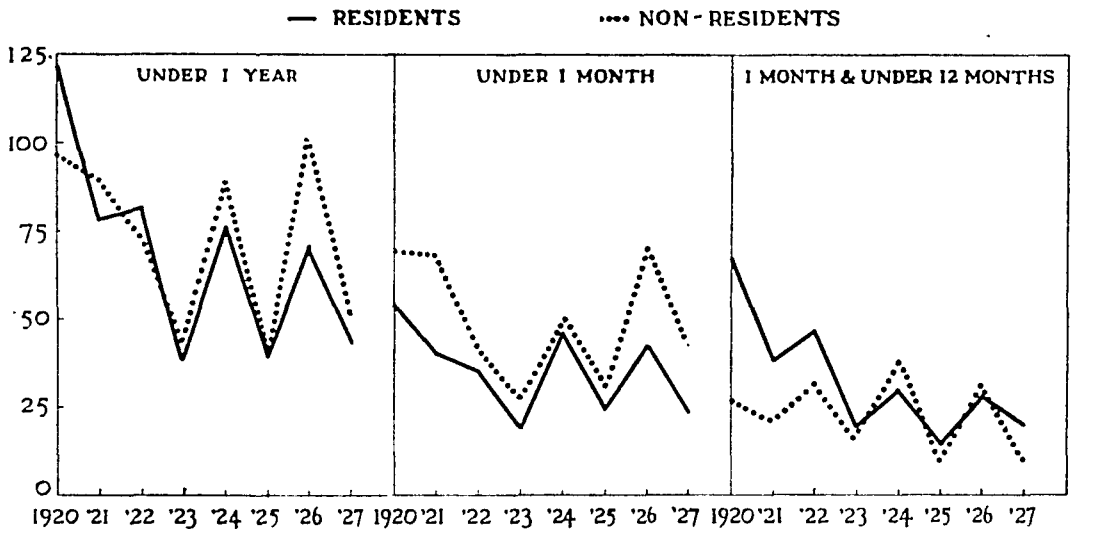
Nephritis (128, 129)	55.3	29.9	90.7
Puerperal causes (143–150)	27.9	8.4	16.2
Congenital malformations and diseases of early infancy (159–163)	135.8	79.2	78.9
Violent deaths, suicide excepted (175–203)	69.0	32.2	82.0

FIGURE I

BIRTH RATES AND DEATH RATES INCLUDING AND EXCLUDING NON-RESIDENTS, FARGO, N. D., 1920–1927



of residents occur outside. This is confirmed for deaths by the resident rates prepared by the U. S. Bureau of the Census following allocation to Fargo of deaths of residents occurring elsewhere in the U. S. Registration Area. In 1924 and 1925 these resident rates were 7.8 and 7.6 respectively—only slightly higher than the rates based on resident deaths used in this study and far below the rates including local deaths of both residents and non-residents.

Infant mortality rates calculated with reference to resident births and deaths and non-resident births and deaths also showed important differences (Figure II). Among non-residents, the total infant mortality rate tended to be higher than the resident rate, especially in the years 1924 and 1926 when both rates were considerably above those for other years in the demonstration period. For infants under 1 month, the non-resident rate was consistently high, as would be expected with the large number of non-resident births and deaths in hospitals, many of which were probably cases with threatened complications brought in from the surrounding area. For the older infants, there is less consistent difference between the non-resident rates and the resident rates.

Mortality rates for certain causes requiring operative or other special care are shown in Table II, and are especially high when non-

FIGURE II

RESIDENT AND NON-RESIDENT INFANT MORTALITY RATES, FARGO, N. D., 1920–1927

residents are included. These rates including non-residents are in most instances high in comparison with rates for the U. S. Registration Area, while resident rates are about the same or somewhat below. Other rates by cause varied less if non-residents were or were not included.

Among non-resident deaths, about 59 per cent were male and 41 per cent female. Among residents there was a smaller proportion of male deaths—55 per cent in comparison with 45 per cent for females. The proportion of male deaths among non-residents was especially high in the group of deaths due to accidental cause.

As shown in Table III, there was a larger proportion of non-resident deaths in the age groups over 5 years and under 55, while the

TABLE III

RESIDENT AND NON-RESIDENT DEATHS BY AGE, FARGO, N. D., 1923–1927

Age	Number of Deaths			Per Cent

proportion of resident deaths was larger in the younger and older age groups.

Among non-residents 26 per cent of the births were illegitimate; among residents about 2 per cent.

It is obvious therefore that tabulations of vital statistics for residents only in Fargo are a better means of measuring health progress.

Another difficult problem in the use of vital statistics for measurement purposes was created by the small number of resident births and deaths each year. For instance, with the number of births and infant deaths in 1926 there was a standard error of 11.58 for the infant mortality rate of 71.1, and in 1927 a standard error of 9.03 for the infant mortality rate of 43.4. Fluctuations in most yearly rates have therefore limited significance in comparison with similar fluctuations in communities with larger populations.

As illustrated in Figure II, there was also a marked tendency for the infant mortality rate to vary within the demonstration period considerably in excess of the expected amount of yearly variation which might be attributed to the small number of cases. In 1924 and 1926 both the resident and the non-resident rates were nearly twice as high as in 1923, 1925 and 1927. These same differences were also present for both residents and non-residents in the mortality rates for infants under and over 1 month.

In a search for possible causes for these wide fluctuations in annual rates, all infant deaths of residents were allocated to the year when the child was born, and yearly rates were calculated on this basis. While this method reduced somewhat the amount of fluctuation, the resident rates for 1924 and 1926 still remained high in comparison with those for other years in the demonstration period.

Detailed study of causes of death during these years showed that in the 2 years with high rates the mortality from congenital causes* and from respiratory diseases among both residents and non-residents was high. In 1924 there were also more deaths from diarrhea and enteritis than in the other years. In 1926, the other high year, there were more deaths due to accidents and other external causes.

In 1923, the first year with a low rate, there were few deaths from premature birth and no corresponding increase in stillbirths from this cause. In 1925 and 1927 the low rates were apparently caused by a fairly evenly distributed reduction in the various causes of infant deaths.

---

* It is interesting to note that in the year 1926 there were 13 infant deaths from comparatively rare abnormalities such as hydrocephalus, spina bifida, anencephalus, foramen ovale, etc., while in other demonstration years there were never more than 4 deaths per year from these causes.

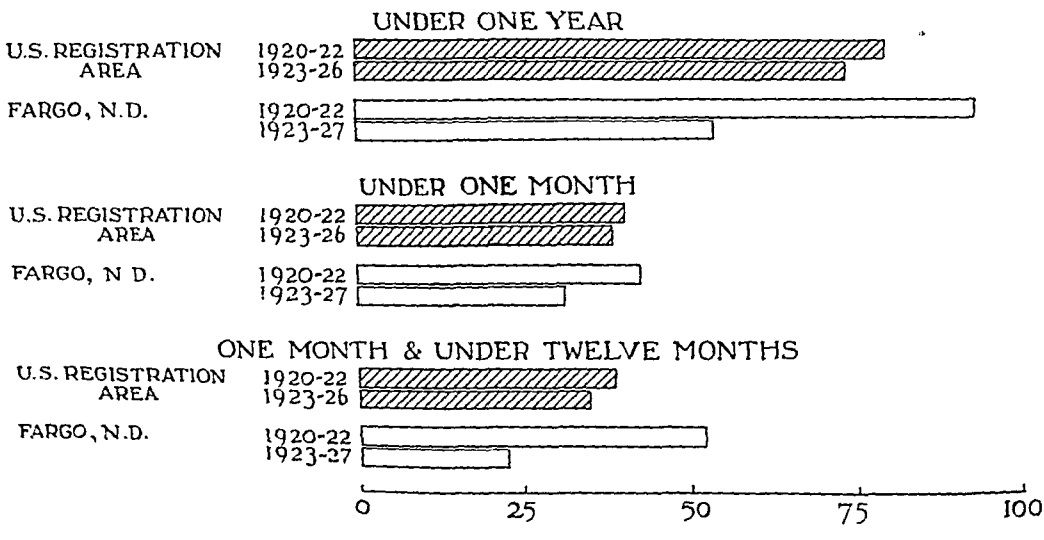
Apparently the wide fluctuations in infant mortality rates during recent years are due to the concentration of various unrelated favorable and unfavorable factors within particular years. If these had shifted but slightly, as, for instance, if the mortality from congenital causes had not happened to be high in a year when the mortality from respiratory causes or from accidents was also high, much of the present variation in rates based on a small number of total deaths would have been eliminated.

Under such conditions neither the high nor the low rates during successive years of wide fluctuation are accurate for use in measuring changes in local health conditions or in making comparisons between local rates and those for other areas with larger units of population. Therefore, the policy finally formulated for the measurement studies was to combine vital statistics for the 5 demonstration years in an effort to eliminate accidental fluctuations in yearly rates. The same policy has also been followed in the combination of data for the 3 pre-demonstration years, the maximum period, as previously described, for which comparable data could be secured.

MEASUREMENT FINDINGS

In certain instances mortality rates as calculated in these measurement studies gave little or no definite indication of health improvement within the demonstration period. Usually these rates were based on a very small number of cases; they were related to conditions which, as experience elsewhere shows, are likely to respond slowly to preventive health measures; or the rates during pre-demonstration years were already low in comparison with those for the registration area. For example, the stillbirth rates in Fargo were 3.7 for the years 1920–1922 and 3.5 for the years 1923–1927, in comparison with corresponding rates of 4.0 and 3.9 for the registration area. The maternal mortality rate (which was based on a total of only 5 maternal deaths in 1920–1922 and 12 maternal deaths in 1923–1927) increased from 3.5 in the early years to 4.8 in the demonstration years but remained considerably below the registration area rates of 7.1 and 6.6 for these periods respectively. Tuberculosis rates were also low—33.8 and 38.6 for resident deaths in the years preceding and during the demonstration period respectively. Careful checking showed that these rates would have been increased but slightly by including the relatively few residents who died outside of the city from tuberculosis.

In other instances, however, mortality rates for Fargo residents during the demonstration years indicated fairly definitely an improvement in the status of community health.



The average infant mortality rate for the years 1923–1927 was 53.5 in comparison with an average rate of 92.9 during the pre-demonstration period—a reduction of about 42 per cent. Among infants over 1 month of age the average mortality rate was reduced from 50.2 to 22.4, or by 55 per cent; for infants under 1 month of age from 42.7 to 31.3, or by 27 per cent. All these later rates for Fargo are considerably below those for the U. S. Registration Area while pre-demonstration rates were relatively high (Figure III).

Study of reduction in infant mortality rates by cause showed, as would be expected, that the reduction has been greatest in the group of causes at present especially subject to known measures of prevention and control. For instance, no infant deaths occurred among Fargo residents within the demonstration period from measles, scarlet fever, whooping cough or diphtheria, although in 1920–1922 the infant mortality rate from these causes was high in comparison with the registration area. In comparison with the pre-demonstration years the infant mortality rate from diarrhea and enteritis for the demonstration years was reduced by two-thirds; from influenza, bronchitis and pneumonia by over one-half; from congenital causes by about one-fourth. All of these reductions were considerably greater than reductions in corresponding years for the registration area.

Mortality rates for preschool children and school children have also been markedly reduced, although the small number of such deaths (see Table III) makes these changes of less significance than those in infant

FIGURE III

AVERAGE INFANT MORTALITY RATES IN FARGO, N. D., IN COMPARISON WITH U. S. REGISTRATION AREA

mortality. For children in the age group 1–4 years, the mortality during demonstration years was 430.4 per 100,000 population in comparison with 683.1 for the pre-demonstration period. For the age group 5–9 years, the demonstration rate was 172.3 in comparison with 252.3 for the pre-demonstration period; for the age group 10–14 years, the demonstration rate was 113.0 in comparison with 207.0. Here also the recent reduction was most marked with reference to epidemic, endemic and infectious diseases, diarrhea and enteritis and diseases of the respiratory system.

As pointed out by Dr. Walker in his appraisal of public health work in Fargo,* the deaths of persons under 20 years of age from certain preventable causes (typhoid fever, diphtheria, scarlet fever, measles, whooping cough, tuberculosis, diarrhea and enteritis, bronchitis and pneumonia) have shown a decrease from an annual average of 33.0 deaths in the period 1920–1922 to an average of 14.8 deaths in the period 1923–1927.

While only a relatively small number of cases are concerned in these comparisons the large difference in most of the rates between the demonstration and pre-demonstration years, the similarity in the downward trend in rates for children in different age groups and the close agreement between the reductions indicated and those occurring elsewhere where preventive health services have been organized, indicate measurable health progress during the demonstration period.

* See Part II, Fargo Final Report, p. 6.

Welfare Work for Young Workers in Austria

AUSTRIA recently celebrated the tenth anniversary of the establishment of the government welfare bureau for young workers. This bureau was organized at a time when the adverse economic conditions of the war period were beginning to affect seriously the health of the majority of the young workers. The main function of the bureau is to provide at a nominal charge vacations in the country for young workers whose health is below par. Homes for this purpose are conducted by the bureau. These homes provide proper food, outdoor exercise, and recreation under the supervision of physicians. The average stay in these homes is four weeks.

The cost of the work is met by contributions from the sickness-insurance funds, appropriations of the national and local governments, and fees paid by the young workers who take advantage of the homes.

During the 10 years of the bureau's existence, over 75,000 young workers have been cared for in the 6 rest homes.—*Lehrlingsschutz, Juggend- und Berufsfürsorge,* Sept., 1928, p. 3.

What We Do Not Know about Accidents*

R. L. FORNEY

Statistician, Public Safety Division, National Safety Council, Chicago, Ill.

ACCIDENTAL deaths will be considered in this paper, disregarding non-fatal injuries, about which our ignorance is even greater than about fatalities. I shall discuss three things that we do not know about accidental deaths: first, how many there are; second, where they occur; and third, their circumstances.

HOW MANY ACCIDENTS

It is quite true that at present we do not know how many people are killed by accident in the United States each year. There are two reasons for this: first, incomplete reporting within the U. S. Registration Area, and second, lack of reports from outside this area. The first is less important than the second, and the second is receiving more and more attention. One evidence of this attention is the slogan printed in red on the stationery of the U. S. Bureau of the Census: "Every State in the Registration Area Before 1930." I feel sure that the conditions which have prevented the remaining few states from entering the registration area will be eliminated within the next two years so that this goal can be reached. When it is reached and we can include 100 per cent of the population of the United States in the registration area, then we shall know more accurately than we do today the number of deaths from accidents, as well as other causes, in the entire United States.

WHERE ACCIDENTS OCCUR

Neither do we know where accidents occur. Two methods of classifying accidental deaths suggest themselves: first, a classification, by type, such as falls, burns, machine accidents, etc.; the other a classification by the place of accident occurrence. In general, the *International List of Causes of Death* follows the first method. With one or two exceptions the International List numbers from 175 to 196 and from 201 to 203 separate different types of accidental injury. An exception to this method is classification 186 A, traumatism in mines;

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-seventh Annual Meeting, at Chicago, Ill., October 16, 1928.

another is 186 B, traumatism in quarries. In these two instances the second method of classification has been followed, namely, a classification by the place of accident occurrence. In other words, an accident in a mine may be a burn, a fall, a machine accident, or other kind. All of these, however, would be classified in 186 A—mine accidents.

This classification by type of injury is quite essential. It supplies information of great practical importance. Its sufficiency as a method, however, must be considered in the light of the fact that statistics covering accidental deaths are not collected for the purpose of discovering what occurred in the past, but for determining what should be done in the future. The most important task of the accident preventionalist is the education of individuals that they may act safely.

There are several spheres of activity into which the life of the ordinary individual divides itself. These are, briefly, home, industrial, and public. There is undeniably a certain similarity among the various things done by an individual in any one of these spheres of activity, guided to a considerable extent by daily habits.

Paralleling this division of activity it is also true that accidents occur where men live, where they work, and in public places. Accident prevention should accordingly be undertaken with this in mind. Two accidents of the same type may be subject to entirely different preventive methods because one of them occurs in a public place while the other occurs in a home. Similarly, two accidents essentially different in type may become similar from the prevention standpoint because they both occur in a home under domestic conditions.

There is a fourth classification of accidents that is frequently made; namely, the separation of motor vehicle public accidents from those public accidents not involving a motor vehicle.

At the present time, information about accidental deaths, classified as suggested here, is not available. To be specific, some 17,000 persons died in the United States in 1927 as a result of falls. Some of these were falls of construction laborers from buildings, others were of men in factories, still others were of persons on floors and rugs in homes. We do not know the number in each of these groups; and this despite the fact that a reasonably exact distribution of all such accidents into the classes mentioned would be of the greatest value in prevention work.

Not knowing how many persons are killed each year in industries, in homes, and in public places, all we can do at present is to estimate them on the basis of meager information. And if more than one agency attempts to make such an estimate there is liable to be a wide divergence of results. Let me repeat that this information is vitally

important. It would make possible, excluding automobile accidents, a separation of each accident classification in the *International List of Causes of Death* into the three groups of public, home, and industrial accidents.

It would of course be insufficient to have such a separation only for the country as a whole. The differences from one part of the country to another are great and significant. Perhaps the outstanding one is the difference between rural and urban sections. We should want, therefore, a complete separation of the rural and the urban experience, covering type of accident as well as place of accident. At the present time we know much less about rural accidents than about urban accidents, because difficulty has been experienced in the past in obtaining detailed accident information except in cities. It is quite certain, however, that this grouping of accidents by place of occurrence would be quite different in country from in city.

We also need to obtain detailed information covering the age and sex of accident victims in each of these three classifications. These things would be of immense value to the safety worker because accident prevention efforts, to be successful, must be directed at specific hazards in specific locations. By the grouping of accidents in the way suggested, the prevention efforts can be correlated with the natural phases of human activity, with much better results than are otherwise possible.

CIRCUMSTANCES OF ACCIDENTS

The vehicular accident reporting card prepared and issued by the National Safety Council is now widely used. I mention this card because it illustrates the idea of obtaining detailed information on circumstances of accidents. In this case the circumstances relate to motor vehicle accidents only. Answers are required to such questions as: "What was the driver doing at the time of the accident?" and under this question such possibilities are suggested as turning right, turning left, passing standing street car, etc., all designed to throw new light on the circumstances surrounding the accident. Another question is: "What was the pedestrian doing?" Still others ask about the road condition, the light condition, and so on. If the conditions and circumstances revealed in such reports are actually used to educate motor vehicle drivers and pedestrians to avoid taking those actions which result in accidents, then we have taken a step toward the solution of the problem.

Information of this kind is needed regarding all types of accidents. Some of it is now available in connection with industrial accidents. In

a few states some of it may be had relative to motor vehicle accidents. But in both of these cases the information is far from satisfactory as representing nation-wide conditions. For public accidents not involving a motor vehicle, and for home accidents, we have almost no such information.

We need to know not only how many falls occurred in homes, but also how these falls occurred; how many of them were falls on stairs and steps; how many resulted from tripping on rugs; how many from falling off porches and from trees, etc. In the classification of home fires we need to know whether the fire was started by a match, by spontaneous combustion, by poor electrical wiring or by something else. Something can be done toward the prevention of falls by simply pointing out to persons that so many occur in homes; but much more can be done if the circumstances under which those falls occur can be accurately set forth.

The same thing is true of public accidents. We need to know how many accidents occur in falls in public buildings, how many result from flying objects of one kind or another, how many from elevator accidents, etc.

From what sources of information may we expect to obtain these facts? Several possibilities suggest themselves: A state industrial commission may be expected to obtain reports of all accidental deaths falling within the scope of the Workmen's Compensation Law. The usefulness of this information is limited to a considerable extent by lack of uniformity in Workmen's Compensation Laws and lack of uniformity between the various states in statistical procedure.

A state motor vehicle department, with a properly prepared law requiring reports of motor vehicle accidents, may obtain rather complete information on motor vehicle deaths. In some 8 or 10 states this is being done in quite a satisfactory fashion.

The insurance companies are in a position to obtain complete and accurate information on such deaths as occur to their policy holders. The limitation here is the obvious one that not all persons in the country are insured.

A review of these and other sources shows them to be inadequate for our purpose. If a complete record of accidental deaths in any state, community or nation is wanted, we must turn to the officials who receive, by law, reports on all accidental deaths.

To do this job in a complete fashion will require a certain amount of additional procedure on the part of registrars of vital statistics. This is because the death certificate, as at present constituted, will not reveal the information which is outlined as desirable for accident pre-

vention purposes. While this certificate does make possible complete reporting on deaths by disease, the detailed reporting of accidents must be accomplished by some new means.

What has been done in this direction? I shall attempt to tell you very briefly. About one year ago, A. A. Whittemore, M.D., State Health Officer of North Dakota, and an officer of the North Dakota State Safety Council, wrote to me pointing out how meager was the available information on accidents for use by the North Dakota Safety Council in its prevention work in that state. At that time he asked the coöperation of the National Safety Council in proposing some method whereby he, as head of the State Health Department and Registrar of Vital Statistics, could obtain complete and detailed information on at least fatal accidents in his state.

After an exchange of correspondence a proposal for a supplementary accident reporting form was made through my office. Dr. Whittemore, with characteristic energy, printed a quantity of these forms and immediately put them to use in North Dakota, requiring in every case of accidental death a report on this form in addition to the usual death certificate. Shortly after that time, as the news of this pioneering job spread to other states, James E. Bauman, Assistant Director of the Ohio State Health Department, wrote of his interest in doing this same thing for the State of Ohio. The proposed reporting form was brought up to date and was given a trial of several months in that state. Very recently the proposition has also been taken up in the State of Arkansas.

This suggested reporting form is far from perfect. Changes in it will undoubtedly be necessary as a result of experience. It is true, however, that the form is not a radical departure from similar work that is being done. The information requested on motor vehicle accidents, for instance, corresponds exactly with the work being done in the traffic accident field by some 60 cities and 8 or 9 states with compulsory accident reporting laws. The section pertaining to industrial accidents is the same as that recommended by the U. S. Bureau of Labor Statistics. In all other respects the reporting form was designed so that the information obtained would be comparable with any that is being obtained in other ways. A punch card for use in mechanical tabulation has also been developed; and forms are available which facilitate an analysis of the information.

It is my hope that this plan will be tried out by many more states. I am sure that as its use spreads, resulting in much new data, we will see reductions in accidents.

DISCUSSION

E. S. MACPHAIL, FELLOW A. P. H. A.

Superintendent, Census and Vital Statistics Branch, Bureau of Statistics, Ottawa, Can.

THE first purpose of classifying deaths from accidents is the separation of these and of other violent deaths from the deaths which are due to natural causes. The classification of accidental deaths according to the nature of the injury does not in general seem to be of first rate importance. It is of interest to know how many die from fracture of the skull, how many from the piercing of internal organs, how many from broken ribs, etc.; but this classification would take on its main usefulness in connection with a knowledge of the total number of cases, so that a case rate could be reached. Standing alone it does not seem to merit an adoption as the general principle of subdivision. The main object in a classification of accidents is their prevention, and it may be that by not going far in the subdivision of this class, the International List limits its own usefulness.

It has also to be noted, as Mr. Forney states, that the classification is not on a uniform basis. In addition to accidents in mines and quarries, where the type of locality instead of the type of accident is the criterion of classification, there are also such rubrics as "accidental mechanical suffocation," and "accidental drowning," which describe rather the manner than the circumstances of a death. This also applies to "accidental burns and scalds," except that in this case the caution is inserted (except those resulting from conflagration, the latter, number 178, being classified on a different basis). The death is attributed to conflagration whether it is by burning, suffocation, a fall, or by being trampled upon in trying to get out of a building.

To take, for example, drowning, it seems fairly clear that to point a lesson for prevention, further details are required. It should be ascertained whether the victims were swimming at the time of the accident, were in pleasure boats or in larger vessels, or whether these accidents were industrial in their nature, that is, whether those involved were fishermen, sailors, etc. We do not tabulate this kind of information and do not as a rule even possess it. Of 298 cases of deaths from accidental drowning in the Province of Ontario in 1926, 14 were given as industrial in their nature—sailors, fishermen, river drivers and lock masters; 9 were drowned while swimming and 9 in some other stated manner. In no fewer than 253 cases the record failed to give any details beyond the statement that the decedent was drowned.

Mr. Forney's suggested division of accidents into three classes—in industry, at home and in public places, appears to have a great deal of significance. Presumably prevention of accidents in industrial life will be largely attained by inspection of premises and regulation of safety appliances; prevention in public places may be largely a matter of regulation regarding traffic, overhanging signs, etc.; but it may also depend on care exercised by public servants as in the matter of clearing slippery streets, maintaining adequate protection against the danger of falling into excavations, taking proper precautions in the matter of demolition of buildings, etc., etc. On the other hand, the prevention of accidents in the home environment will depend almost wholly upon individual precautions, and the work of the preventionalist must here be confined in the main to education.

If, however, accidental deaths are to be published under these three headings

an exact definition of the field embraced under each will be required. Industrial accidents do not perhaps offer great difficulty in this respect, although there is certainly a difference between work which is well organized and conducted by a body of men under the leadership of an employer or foreman and that which is carried out by an individual on his own behalf. In the latter case, again, prevention will be mainly a matter of individual precaution. As between home and public accidents there appears to be a borderland in which it would be difficult to say under which heading accidents should be classified.

For example, is it to be assumed that all drownings except the industrial occur in public places (except in the very few cases which occur on the home premises), or is the distinction to be drawn between places such as beaches which are under public regulation and protection and those drownings which occur in more private surroundings such as in unsupervised water?

Some cases are rather embarrassing—for instance, should the passengers who are drowned in a shipwreck be classified as having died of drowning or as having died of accidents of transportation? In the matter of elevator accidents, are all of these to be considered as occurring in public places or would an elevator in a rooming house or apartment house be considered as belonging to the home environment. Falls might offer many cases in which it would be hard to decide to which rubric the death appertains, and on the whole it seems that a good deal of definition would be required before accidents could be tabulated under these headings with any probability of fair comparison between the statistics published by different bodies.

It is apparent that the mere division into environments will not accomplish everything from the preventive standpoint. To see what kind of material we had on hand in our office at Ottawa, deaths from certain forms of accidents for the Province of Ontario for the year 1926 were reviewed. Reference has already been made to the deaths from drowning, but it may be interesting to note what the returns on hand show for several other kinds of accidents.

Of 259 deaths due to falls 74 were shown to have taken place in the home environment. The preventionalist who would wish to effect improvement by means of cautionary literature would, however, need to know more than this. Of these falls, 41 were on steps or stairs, 7 from window, balcony, etc., 11 were falls on a floor and 2 off tables, chairs, ladders, etc. The number of falls, industrial in their nature, amounted to 156; falls in public places numbered 19, of which 10 were falls on pavement, street or ice, 1 was from a height while 8 were of some other nature. In no fewer than 110 cases the information was limited to the fact of a "fall," and the accident could not be further classified.

Deaths from accidental traumatism by machines numbered 46. Of these 5 were due to an elevator accident and 3 were industrial. Corn cutters accounted for 3 deaths, circular saws for 5 and threshing machines for 3; in 30 cases there was no detailed information. It may be presumed that in nearly all cases where an elevator is not involved these accidents from machines are industrial.

Deaths classified under 181, accidental absorption of irrespirable or poisonous gas, numbered 28, of which 16 were credited to carbon monoxide. In 4 of the 16 cases the accident was attributed to automobiles, but in the remaining 12 further information was not available; of the remainder, 4 deaths were charged to coal gas and 7 to illuminating gas. The important feature here seems rather the circumstance than the chemical nature of the gas.

Poisoning by food was given as the cause of 20 deaths. In 12 cases ptomain

poisoning was the cause; in 5 cases deaths were attributed to toadstools and poisonous mushrooms. The number of cases is small but the example is cited as one in which from the standpoint of prevention it is necessary to know the kind of food article responsible for the damage.

Under the Canadian system of classification, deaths in which an automobile figured are classified as automobile accidents whether in the case of a pedestrian struck by an automobile or the collision between an automobile and a train or other vehicle. The total number of deaths coming under the classification of automobile accidents in Ontario for the year 1926 was 242. An examination of these certificates revealed the fact that in 82 cases pedestrians had been killed by automobiles, in 15 cases deaths were due to collision between automobiles and trains, in 6 cases between automobiles and street cars, in 9 cases between two automobiles, and in 3 cases between an automobile and some other vehicle. In 15 cases there was no external contributory vehicle, while in 107 cases the details of the accidents were not given. Motorcycles when stated as the cause have been excluded from the above analysis. It is evident that for a more detailed classification of automobile accidents than is now available in Canada we would have to demand such classification on the certificate (a rather difficult matter, when the form of the certificate envisages deaths from natural causes as well as by violence), or to refer the question back to the local registrar in the manner suggested by Mr. Forney, or to obtain this additional detail from coroners' reports, police reports or other sources.

Mr. Forney points out the necessity of classifying returns of fatal accidents into rural and urban, arguing with considerable truth that conditions surrounding these accidents are likely to be very dissimilar. A difficulty arises here, however, in deciding at what point the distinction will be made, whether by the census definition of rural and urban, or whether the minimum for the higher category should be, say cities and towns of 5,000, 10,000, 25,000 or even 100,000 population. We are embarrassed here between the desirability of making all significant distinctions and the impracticability of carrying the division too far.

Another difficulty arises in this matter. For the movement of population in general, the significant locality is no doubt the locality of residence, and it is customary to tabulate deaths in vital statistics either by the place of residence or by the place where the death occurred. From the standpoint of preventive measures, however, the significant locality for deaths from accident is not necessarily either of these but the place where the accident occurred. Quite recently the Dominion Bureau of Statistics had a communication from the chief constable of one of the Canadian cities taking exception to a tabulation of automobile accidents on the grounds that the figures published for his city included a number of cases in which the accident had occurred beyond the city limits but where the victim had been hurriedly rushed to a city hospital in an attempt to save life. The bulletin giving the figures complained of contained a caution on this very subject but the difficulty remains. It may be argued that this is properly a matter for police statistics, and not for vital statistics; nevertheless, if accidents are tabulated with a view to present the information in the best form for preventive purposes, the locality of occurrence takes on especial interest.

Mr. Forney has referred to the classification of industrial accidents and the possibility of obtaining reports on deaths of this nature when they fall within the scope of workmen's compensation laws. In Canada the Federal Labour Department pursues a more ambitious policy and endeavors to collect particulars of fatal (as well as of non-fatal) industrial accidents.

The Labour Department gathers its information from a variety of sources, including press clippings, and attempts even to cover the field of agricultural accidents. It must be admitted, however, that statistics compiled from such heterogeneous sources can be made complete only at the cost of exhaustive labor, and it seems unfortunate that with records presumably covering all except a negligible number of the accidental deaths in the country these records cannot be made available for the purposes of compiling industrial accidents.

If a scheme such as Mr. Forney suggests is followed, difficulties will no doubt arise as to the degree of detail in which statistics of accidental deaths can be collected and published. The form suggested by him is very detailed with regard to vehicular accidents, and at the present day it is very proper that a great deal of attention should be centered on this type of accident. In so far as other accidents are concerned, however, it might be suggested that necessary details are neglected. There is no inquiry designed to show under what circumstance an accident may have occurred; in public accidents the rubric, "buildings and structures," appears somewhat inadequate; street accidents "non vehicular" also appears a somewhat indefinite type; and in home accidents no distinction is made between the kinds of falls.

These things are mentioned, not as criticism, but to illustrate the difficulties which will arise if the vital statistician goes beyond the International List in determining at what point practical considerations must put a stop to further subdivision of classes of accidents.

After the registration of the cause of death in the usual manner it appears probable in accordance with Mr. Forney's suggestion that this second form (one referred to as being used in North Dakota and Ohio to obtain supplementary information) also should be completed by the local registrar as he is in the best position to know whether the information can be obtained from a police report or a coroner's report, or whether he must go to other sources. It will, however, be apparent that this is thrusting additional work on a class of men whose duties as registrars are usually incidental to the tenure of an office of a municipal nature. Whether these additional duties will be welcomed with such zeal as to promise their conscientious performance is a question which may well arise. This is of course a matter not for the federal but for state and provincial offices both in United States and in Canada.

Consultation Center for School Children Suffering from Heart Disease in Berlin, Germany

A MUNICIPAL consultation center for school children with heart disease was recently established in Berlin. At this center, school children are examined before they are allowed to engage in long hikes, swimming or other sports, or gymnastics, and also before they select an occupation.—*Zeitschr. f. Kinderschutz, Familien- und Berufsfürsorge,* Vienna, Sept., 1928, p. 146.

Symposium on Schoolroom Ventilation*

Reports on Schoolroom Ventilation Studies

NEW HAVEN, CONN.

LEONARD GREENBURG, PH. D., FELLOW A. P. H. A.

U. S. Public Health Service, New Haven, Conn.

THE frequency of the common cold among adults throughout this country is so high that one hardly requires a statistical treatment of this subject to become aware of the importance of this problem. Recent studies of the U. S. Public Health Service[1] show that respiratory diseases account for 47 per cent of all the cases of illness reported in a large industrial group during a 5-year period. Among school children the problem is one of greater magnitude, for the child is more susceptible to respiratory diseases than is the adult.

Evidence has been slowly accumulating, which serves to show that the method of ventilating the schoolroom has an important bearing on the health of the school child as measured in terms of respiratory disease rates.

In the first study of this subject made by the New York State Commission on Ventilation the findings appeared to us to be of considerable importance. For this reason the study to be described was inaugurated in the fall of the year 1926.

The present study was conducted in 7 schools of New Haven, Conn., by permission of the superintendent of schools and with the assistance of members of his staff to whom we are indebted.

The desideratum was of course to select schools of both types (mechanically and naturally ventilated), situated geographically as closely as possible together in order to study pupils from homes having the same social and economic backgrounds. In addition, it was essential to obtain the best examples of the types of ventilation under study that the city had to offer. The final selection of the 7 schools, 4 mechanically ventilated and 3 window ventilated, represents the most satisfactory choice from these points of view.

The 4 mechanically ventilated schools are between 14 and 26 years old, the average being 19 years. These schools are all two stories in height, made of brick with cement and wood floors and ventilated by a

* Presented before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 15, 1928.

fan located in the warm air chamber. In a few cases accessory direct radiation is provided. The warm air enters the classroom by means of a duct, usually approximately 25 x 30 inches, located near the ceiling, and leaves the room by a 25 x 30 inch register located at the floor level. In the case of one of the mechanically ventilated schools (Worthington-Hooker), heating and ventilation is accomplished by the univent system.

The 3 window ventilated schools are all older than the mechanically ventilated ones. They average 54 years of age, varying from 39 to 65 years. Heating is in each case accomplished by direct radiation in general placed on the outside walls of the rooms but not in accord with the very best practice with respect to the location of windows. The windows are generally provided with slanting window boards. The gravity exhausts from the schoolrooms vary from 12 x 18, to 24 inches square. In most cases these are at the floor level and for this reason do not adequately meet the requirements of this type of system.

ORGANIZATION AND CONDUCT OF STUDY

In all, 3,596 pupils were under observation in this study, 2,052 in the 4 mechanically ventilated schools and 1,546 in the 3 window ventilated buildings. The study was begun in December, 1927, but because of the extended vacation, we have only utilized data from January 3 to April 1, inclusive.

Absences were reported on a form devised for this purpose. All the teachers were required to submit the cause of absence for every child away for one-half day or longer. The teacher in this instance determined the cause of absence from the child, from the parents, and in some cases by notification from the family doctor. In addition to these data concerning all absences, we have been able to obtain a complete set of absolutely independently collected data concerning absences of a duration of three days and more. In this case the diagnosis was made by the doctor or health department nurse. These data were obtained through Dr. C. C. Wilson, a student in the Yale Medical School, who was then engaged in a study of school absences in all the schools of New Haven, Conn. The present study, therefore, makes use of two independently collected sets of data, one of all absences and one of absences of three or more days' duration. Throughout this study we have considered respiratory illnesses to consist of colds, sore throat and other affections of the respiratory tract, such as pneumonia, bronchitis, etc.

By means of a suitable mimeographed record, we collected data from the schools, showing the number of children who while in at-

tendance appeared to be suffering from respiratory disease. The value of these data is in our opinion highly questionable, and for this reason we are not reporting them at this time. Information concerning the temperature of schoolrooms was obtained by observation either by the teacher or one of the pupils of the dry bulb thermometer four times during the course of the school day. These temperatures were recorded on the mimeographed form provided for this purpose.

At the start of the study the teachers were impressed with the importance of learning the true cause of absence and of reporting the true temperature of the schoolroom. At no time were instructions or suggestions issued to the teacher or any other of the operating officials concerning the management of ventilation systems or the proper temperature to be maintained in the schoolrooms. The test was devised as a study of actual operating conditions as found in the ordinary schools of an average American city.

THE RESULTS OF THE STUDY

As pointed out earlier, it is highly important that the two groups of schools be comparable with respect to age group and nationality. The first analysis of our material disclosed the fact that the mechanically ventilated schools had an average percentage of 29.9 pupils of American parentage as contrasted with 15 per cent in the window ventilated group. For this reason we examined our data and eliminated from the mechanically ventilated group the Worthington-Hooker School which possesses a very high population of American parentage (70.8). The elimination of this school with its univent system served also to make the ventilation of the mechanically ventilated group more nearly of uniform character and finally yielded a mechanically ventilated group of schools having an average of 17.5 per cent of pupils of American parentage as contrasted with 15 per cent in the naturally ventilated group. From this viewpoint, the two groups are highly comparable. The age factor is also of much importance and our two groups now possess pupils of highly comparable age, 7.9 in the mechanically ventilated group and 8.6 in the naturally ventilated group of schools.

Examination of these two groups of schools reveals the fact that the number of pupils in each group is approximately the same, 1,573 as compared with 1,546; the total number of pupil sessions is very nearly the same, 180,000 and 187,000; the mean weighted daily temperature is 67.6 in the mechanically ventilated group and 68.1 in the naturally ventilated group of schools. In all of these foregoing respects the two groups of schools are very nearly alike. The data for

absences, however, in these two groups of schools show striking differences. The mechanically ventilated group suffers a total absence rate (all causes) of 6 per cent of the total pupil sessions, whereas the naturally ventilated group has a rate of 3.9. All absences due to respiratory disease amount to 3.0 per cent in the mechanically ventilated group and 1.8 in the naturally ventilated group. For three-day and more absences due to respiratory illnesses, the rate in the mechanically ventilated schools is 3.3 per cent and in the naturally ventilated schools is 1.2 per cent.

The observed differences in these two groups of schools cannot be ascribed to differences in age distribution for, in the same grades (and hence about the same ages), the respiratory disease rate is higher in the mechanically ventilated schools than in the naturally ventilated ones, the actual figures being the following from the 1st grade to the 6th inclusive. For the mechanically ventilated schools 5.0, 3.8, 3.8, 2.8, 2.1, 2.3, 2.0; for the naturally ventilated schools 3.7, 2.0, 1.8, 1.6, 1.9, 0.9, 1.3. In each one of the corresponding grades, the rate in the naturally ventilated schools is lower than that in the mechanically ventilated ones.

In attempting to make certain that the origins of these absences have been truly established, we have analyzed the three-day absences into the following groups: all causes, respiratory illness, other illnesses and other causes. It was found from this analysis that the mechanically ventilated schools showed an excess of 5,000 pupil sessions absence due to all causes, approximately 4,000 of which were due to the excess of respiratory illnesses in the mechanically ventilated group over the naturally ventilated group; approximately 650 pupil sessions were ascribed to other illnesses, and but 350 pupil sessions to other causes. In other words, there was a very slight excess in absences in the mechanically ventilated group due to other causes (an amount equal to but two pupils absent during the course of the entire study), a somewhat greater amount of absences due to other illnesses, but still a comparatively small number, and a real excess of absences (approximately 4,000) due to respiratory illness.

Of the fallacy involved in the use of even weighted average temperatures, we are quite aware. Studies of the distribution of temperature in the schoolrooms failed to yield any information which would tend to indicate that there were significant differences existing between the rooms in this regard, and as pointed out earlier the average weighted temperatures failed to yield any significant differences. No investigations have been conducted of humidity or air motion in any of the schools under study. This remains for the future. It may well

be that the significant differences between the conditions maintained by the two systems of ventilation are linked up possibly with humidity and most likely with air motion.

CLEVELAND, O.

LYMAN W. CHILDS, M. D.

Supervisor of Health Service, Board of Education, Cleveland, O.

REALIZING that the incidence of respiratory affections among pupils and teachers presents a major problem, we decided to make a study in Cleveland of the effects of the two common types of ventilation—the forced draft system, and the open window type—upon the incidence of respiratory diseases and their sequelae among school children.

The plan previously used by the New York Commission on Ventilation in similar investigations offered a method of study. It was intended that the information secured should supplement the information this body had already accumulated in similar and previous investigations. In order to coöperate more fully with the Commission, their secretary, Thomas J. Duffield, was invited to meet with our committee. He subsequently rendered invaluable aid.

In practically all of the older school buildings in Cleveland, the ventilation is by open window. In the newer buildings situated in the outskirts of the city, the ventilation is by fan. Our first problem was the selection of the school buildings. There was no money available for the modification of the open window rooms. We, therefore, failed to comply with the recommendations of the Commission in the equipment of these rooms with gravity ducts and window deflectors. The buildings included in the study are as follows:

Harvard and Oliver Hazard Perry have split-steam systems with direct radiation and automatic regulation providing six changes of air per hour in accordance with the Ohio State Code, using 2 heat inlets into each room on the corridor side, 8 feet above the floor, 2 exhaust outlets at the floor line on the corridor side. No building has air washers or artificial humiditation. (Harvard has 11,970, and Oliver Hazard Perry 8,920 cubic feet per room, exclusive of cloakrooms.)

Sowinski will be interpreted as having window air supply, gravity vent flue and direct radiators under windows without automatic regu-

lation and without window deflectors in all windows. (Sowinski has a capacity of 11,770 cubic feet per room exclusive of cloakrooms.)

Broadway may be interpreted as having window air supply, but no vent flues with direct radiators under windows, without automatic regulation and without window deflectors. No changes were made in any buildings, nor in the composition of the population of these buildings, to bring the various elements of the experiment under more complete control. (Broadway has a capacity of 11,970 cubic feet per room, exclusive of cloakrooms.)

The schools were well matched for composition of population as to age and grade, social and economic status and national and racial origin.

The regular mental testing program of December, 1927, indicates that the schools which are mechanically ventilated have a somewhat less intelligent population than the schools which were naturally ventilated.

The committee in charge of the study discussed the factor of intelligence and decided to neglect it entirely as of no particular consequence. Since the results are favorable to the more intelligent group as well as to the naturally ventilated schools, it may be well to make note of the fact here.

The study was made in February and March, 1928, using the forms and following in the main "The Methods of Analysis" of Thomas J. Duffield.[1]

The method of determining the incidence of respiratory disease was made uniform throughout by the careful supervision of the Health Service Department of the Board of Education and the coöperation, under the direction of this department, of teachers, supervising nurses, and attendance officers. It was found convenient in the operation of this experiment to consider Sowinski open window building and Oliver Hazard Perry fan building as Group I; Broadway open window and Harvard fan building as Group II.

Two nurses devoted their entire time to instructing the teachers and investigating the cases present with respiratory diseases. The nurses in turn were instructed and supervised by the supervisor of health service. One nurse was assigned to Group I and one to Group II, alternating at the end of each week. Difficulty was experienced by both teachers and nurses in detecting slight colds. They were instructed to report or record no pupils present with a cold who did not have well marked symptoms, such as conjunctivitis, reddened throat, discharging nose, and voice symptoms, possibly coupled with coughing and sneezing. In other words, children with doubtful symptoms were

not asked to hold up their hands and acknowledge that they did or did not have colds, but regularly filed in front of the teacher, instructed by the nurse, who closely observed the cases.

Doubtful cases were reëxamined by the nurse. Teachers and nurses had one thought in mind, and that was to arrive at an analysis of the truth. Field visitors, middle-aged women from the attendance department, were given the same instructions as the nurses and, in accordance with these instructions, they daily determined and reported the cause of absences when they had visited the homes. They alternated their groups at the end of each two weeks so one visitor would not remain longer than that in one group of schools.

SUMMARY OF DATA

	Natural Ventilation Sowinski and Broadway	Fan Ventilation Harvard and O. H. Perry
1. Period of study	Feb. 6 to Mar. 23, 1928	Feb. 6 to Mar. 23, 1928
2. Pupil sessions, number	72,025	60,392
3. Pupils present and absent with respiratory diseases, expressed in sessions	4,649	7,890
4. Percentage	6.5	13.1

It will be seen that respiratory ailments among pupils present and absent were twice as frequent in the fan ventilated rooms as in the rooms with natural ventilation.

In comparing the two types of ventilation in reference to pupils absent with respiratory diseases, the difference found is insignificant. The same is true for total absences for all causes (see Table II). The 4 schools studied represented highly mixed race stocks, although they were well matched for composition of population (see Table I). In mixed race stocks, absenteeism is likely to be due to causes other than illness. Truancy particularly is likely to be greater.

In the Cleveland schools, a monthly bulletin of school attendance is issued by the superintendent's office. The school with the best daily attendance is first upon the list. Principals in their zeal for a good attendance discourage absenteeism on account of colds, unless they are of a serious nature. Moreover, the practice of absenting children from attendance in schools because of colds varies greatly in different localities. Some of the intelligent parents are in the habit of giving their children bed rest during the first day or two of an attack of acute coryza. Other parents pay no attention whatever to a cold and completely ignore its presence in sending their children to school. On the other hand, children present with a respiratory disease in school can be readily detected by teachers, nurses, and doctors.

The chief of the Bureau of Reference and Research of the Cleveland Public Schools in his statistical treatment of the collected data

endeavored to eliminate the element of chance in comparing the types of ventilation in their influence upon health. This chance element was seized upon by the conservative members of our committee as offering the possible explanation of the results of the experiment. In order to reduce to a minimum this accidental element, differences between schools and groups of schools in illogical combinations and arrangements were tabulated.

As an additional check, each building included in the Cleveland study was pitted against every other building regardless of the type of ventilation. The difference found between Harvard and Oliver Hazard Perry combined (mechanically ventilated) on the one hand, and Sowinski and Broadway combined (naturally ventilated) on the other, was more than twice the difference found between Sowinski and Oliver Hazard Perry combined, and Harvard and Broadway combined. No difference between schools or groups of schools compared accidentally or illogically was so great as the smallest difference between schools logically compared.

In all probability, then, the differences found are not due to mere chance, but represent real differences, reasonably certain to be due to differences in the ventilation of the buildings.

It has been stated that, for the purposes of our experiment, the only rooms available as open window rooms were in schools of an old type. The cubic capacity of these rooms is somewhat greater than that of rooms in modern school buildings. Thus, Broadway's rooms had 11,970 cubic feet capacity each, exclusive of cloakrooms; Sowinski, 11,770; Harvard, 10,690; Oliver Hazard Perry, 8,920. Broadway furnished 298 cubic feet per pupil; Sowinski, 294; Harvard, 267; Oliver Hazard Perry, 223.

The incidence of colds in these rooms proved to be in an inverse ratio to the number of cubic feet per pupil; thus, Oliver Hazard Perry, furnishing the smallest number of cubic feet per pupil, showed 17 per cent of colds; Harvard with 267 cubic feet showed 10.4 per cent; Sowinski with 294 showed 7.7 per cent; Broadway with 299 showed only 5.4 per cent.

The rooms with the greatest air capacity per pupil made the most favorable showing. On the other hand, there was a distinct correlation between the amount of air change and the number of colds. The most modern fan building, Oliver Hazard Perry, with the greatest air changes (6 changes per hour), showed the greatest incidence of respiratory diseases. Harvard, with a less modern ventilation equipment and presumably with an air change of somewhat less than 6 per hour, was next in order of respiratory diseases. Sowinski, a school with in-

sufficient air ducts near the floor, and with considerably less air change, was next in order, while Broadway, with no exhaust ducts, and but a feeble air change, showed the fewest number of colds.

Dry bulb thermometers were used in all schoolrooms under observation. The temperature was taken by monitors (pupils appointed by the teacher for this purpose), whose duty it was to read at intervals the thermometer suspended from the ceiling in the center of each schoolroom to a point just above the heads of the children. These monitors read the temperature at stated intervals and recorded it. When a room in the open window classrooms was found to be overheated, the monitors threw open the windows until the temperature had dropped to normal or below. In the fan ventilated buildings, the custodian was notified concerning an overheated room. In the mechanically ventilated classrooms, the temperatures were fairly steady, while in the open window classrooms the temperatures were variable. This was particularly the case in the Broadway School, which showed the best results and which has been noted for a variable classroom temperature.

It is generally conceded that the humidity of the fan ventilated classrooms was lower than the open window classrooms. This is generally true of all fan ventilated school buildings in the city of Cleveland in which a humidifier has not been installed. The results of the experiment show a greater prevalence of colds in classrooms with the lowest humidity.

1. Duffield, Thomas J. School Ventilation Studies of the New York Commission on Ventilation. *Am. School Bd. J.*, Jan., 1928, p. 57.

SYRACUSE, N. Y.

THOMAS J. DUFFIELD

Executive Secretary, New York Commission on Ventilation, New York, N. Y.

THE School Ventilation Study in Syracuse was inaugurated during 1926. The first year's work has been described in numerous articles[1,2,3,4] which give information concerning the organization and method of study.

The study during the school year 1927–1928 followed the same general lines as during 1926–1927. There were, however, several differences worth noting. These may be summarized as follows:

1. Twelve schools with 4 different types of ventilation were included in the second study as against 6 schools and 3 types of ventilation in the first.

2. Respiratory illness among the pupils was taken as the criterion in the second study as in the first, but in the latter year the school nurses determined the inci-

dence of such illness among the pupils present, a function performed by the teacher during the earlier study.

3. In addition to the data on absences due to respiratory illness, absenteeism due to other illness was also recorded during the second year.

4. More complete data on air conditions in the classrooms were collected by a trained observer during the second year.

It should be pointed out that none of the schools included in this study complies with the recommendations of the earlier Commission. The new window ventilated schools in Syracuse have central fan exhaust systems which created, in so far as the rate of air change was concerned, conditions approaching those obtained by means of fan supply and exhaust systems.

The types of ventilation which have been under observation may be classified as shown in Table I.

TABLE I

NUMBER AND TYPE OF VENTILATION OF SCHOOLS INCLUDED IN THE SCHOOL VENTILATION STUDY, SYRACUSE, N. Y.

Type of Ventilation		Number of Schools	
Supply	Exhaust	1926–27	1927–28
Fan	Fan	2	4
Fan	Gravity duct	1	3
Window	Fan	0	2
Furnace	Gravity duct	3	3

By an arrangement with the Syracuse Board of Education through the School Health Service, under which the Commission provided supplementary nursing service during the year, it was possible to have the school nurses collaborate more closely with the study than during the previous year. The nurses kept the attendance and health record forms on which they entered for each session for each classroom included in the study:

1. Number of pupils on the active roll
2. Pupils present
3. Pupils absent
4. Pupils present with respiratory illness
5. Pupils absent because of respiratory illness
6. Pupils absent due to other illness

The information concerning the first three of these items was obtained from the teacher. By inspection of the pupils and questioning the teacher, the nurse determined the number of pupils present who in her opinion were affected with cold or sore throat. This provided the data called for in item 4. From physicians' certificates, excuses sent in by parents, and home visits, the nurses determined the number of pupils absent because of respiratory and other illness, required by items 5 and 6.

One of the serious deficiencies of the preliminary study of 1926–1927 was the lack of sufficient data on air conditions in the classrooms.

The teachers had kept a record of the dry bulb temperatures, but there was during the earlier study only a single series of observations of the relative humidity and the temperature distribution in the different classrooms, and there was no record of the rate of air change; nor of the air velocities in the different parts of the room.

During the second year, the teachers recorded the temperatures as during the first year. Through the generosity of the Taylor Instrument Companies, it was possible to install a dry and a wet bulb recording thermometer in one classroom of each school during the second study, and it is expected that these records will be extremely helpful in determining the air conditions prevailing under the different types of ventilation and in the different schools.

In addition to these records, the Commission was fortunate in having the services of an extremely able research engineer, Margaret Ingels, M.E., formerly a member of the staff of the Research Laboratory of the American Society of Heating and Ventilating Engineers, who during routine visits to the classrooms made the following observations:

1. Temperature distribution:
   a. Desk top temperatures at the corners and at the center of the seating section
   b. Floor temperature at the center of the seating section
2. Relative humidity:
   a. Sling psychrometer readings in two corners of the classroom
3. Rate of air change:
   a. Vane anemometer readings at supply and exhaust ducts
4. Air velocities:
   a. Kata thermometer readings at two corners of the seating section

Unfortunately, it has not yet been possible to complete the analysis of the attendance and health records with reference to these various air conditions, and for that reason this report will not deal with this phase of the subject.

The 1926–1927 study having indicated a rather close correlation between the incidence of respiratory illness in the mechanically ventilated schools and precipitation (see references 2, 4 and also "The Weather and the Common Cold," Report to the Committee on Public Health Climatology, Vital Statistics Section, American Public Health Association, 1928 *), the attendance and health records from the 1927–1928 investigation are being studied in the light of outdoor weather conditions as reported from the Syracuse Station of the U. S. Weather Bureau. This also is one of the phases of the analysis of the data that has not been completed at the time of this writing.

* See p. 1, this issue, "The Weather and the Common Cold.

As the analysis of data from the 1927–1928 study in Syracuse has not been completed, it is impossible to render a complete report at this time. There are, however, certain phases of the study that may be commented upon now, with the provision that such comments are tentative and subject to revision.

Table II shows the average number and average age of pupils and their percentage distribution by sex and nationality of parents for each school and type of ventilation included in the study during 1927–1928. The 6 schools included in the study during the first year were: Danforth, Seymour, Salem Hyde, Merrick, Montgomery and Townsend.

TABLE III

CRUDE ATTENDANCE AND HEALTH RECORDS BY TYPE OF VENTILATION

School Ventilation Study, Syracuse, N. Y., 1926–1927 and 1927–1928

School Year	Total Absences	Abs. Due to R. I.	R. I. among Pupils Pres.	Total Incidence R. I.
	Total Attendance and Health Records [1]			
Mechanical Ventilation (Fan-Fan and Fan-Gravity)				
1926–27	7.2	3.0	12.6	15.6
1927–28	7.0	2.2	2.7	4.9
Mean	7.0	2.4	5.4	7.8
Natural Ventilation (Furnace-Gravity)				
1926–27	4.9	1.8	7.0	8.8
1927–28	5.7	2.1	4.2	6.3
Mean	5.4	2.0	5.4	7.4
Window-Fan				
1926–27	—	—	—	—
1927–28	9.0	2.4	2.5	4.9

1. Rate per 100 pupil sessions.

The rates of total respiratory illness given in Table III suggest that, while the naturally ventilated, furnace-gravity schools appeared to be clearly superior to the mechanically ventilated schools during the first year of the study, this does not hold true during the second year.

The rates for the two years show the total incidence of respiratory illness to be 5.4 per cent higher in the mechanically ventilated schools; the rates of respiratory illness among the pupils present are identical in the two types of ventilation, while the rate of absenteeism due to respiratory illness is 20 per cent higher in the mechanically ventilated schools (2.4 per cent vs. 2.0 per cent).

Analysis shows the great fluctuations between the findings in the two years to lie in the rates of respiratory illness among the pupils present in the classroom, although the absenteeism reported due to respiratory illness is 26.7 per cent lower in the mechanically ventilated schools and 16.7 per cent higher in the naturally ventilated schools during the second year.

A test, the details of which need not be examined at this time, showed that the influence of the personal equation of the nurses, who were making the inspections of the pupils present in the classrooms to determine the incidence of respiratory illness, was so great as to invalidate any conclusions based on comparisons of their reported findings. This leaves the absenteeism reported due to respiratory illness as the sole reliable index for judging which of the methods of ventilation is more conducive to the health of the pupils.

From the 1926–1927 study, it appeared that absences from school because of respiratory illness were much more frequent among pupils of American families, whereas the rate of respiratory illness among

pupils present was higher in the schools attended by pupils of foreign parentage. The same finding appears to be true during 1927–1928 as shown in Table IV.

TABLE IV

SUMMARIZED ATTENDANCE AND HEALTH RECORDS [1]

By Race Stock of Pupils

School Ventilation Study, Syracuse, N. Y., 1927–1928

Race Stock of Pupils	Total Absenteeism	Absences Due to Respiratory Illness	Respiratory Illness among Pupils Present	Total Respiratory Illness
Italian	4.0	1.6	10.5	12.1
American	6.7	2.7	1.9	4.6
Numerous	8.6	1.9	2.3	4.2
All Schools	7.2	2.3	2.9	5.2

1. Rate per 100 pupil sessions.

Absenteeism due to respiratory illness is a reliable index only when comparisons are made between schools attended by pupils of approximately the same racial characteristics. In view of the fact that 2 of the 3 mechanically ventilated schools in the Syracuse study during the first year, and 4 out of 7 such schools during the second year were attended by pupils largely of American parentage, whereas only 1 of the 3 furnace-gravity schools is attended by pupils of this group, it would be manifestly unfair to condemn mechanical ventilation simply because the schools with that type of ventilation showed higher rates of absenteeism due to respiratory illness. The data must be examined with reference to both the race stock of the pupils and the type of ventilation. Table V presents the information in this manner.

TABLE V

ABSENTEEISM DUE TO RESPIRATORY ILLNESS [1]

By Race Stock of Pupils and Type of Ventilation

School Ventilation Study, Syracuse, N. Y.

Type of Ventilation	All	Race Stock: Italian	American	Mixed
		1926–27		
Fan-Fan	2.9	—	3.5	2.5
Fan-Gravity	3.4	—	3.4	—
Furnace-Gravity	1.8	1.0	2.4	2.0
All	2.5	1.0	3.2	2.3
		1927–28		
Fan-Fan	1.9	1.9	2.2	1.7
Fan-Gravity	2.7	—	2.7	—
Window-Fan	2.5	—	3.3	2.0
Furnace-Gravity	2.1	1.2	2.5	2.2
All	2.2	1.6	2.7	1.9

1. Rate per 100 pupil sessions.

This table brings out the following interesting facts:

1. The schools attended largely by pupils of Italian parentage made the best showing both years, those with American pupils the worst, while those with pupils of many races occupied the intermediate position. This justifies the separate treatment of these groups.

2. In the various racial groups, the furnace-gravity schools made the best showing during the first year. This is also true of the schools attended largely by pupils of Italian parentage in the second year.

3. In the American group during the second year the school with fan supply and fan exhaust made the best record with the furnace-gravity school next, the schools with fan supply and gravity exhaust third, while the new school with window supply and fan exhaust was highest.

4. In the schools attended by pupils of numerous races, the fan-fan school had the best record during the second year, the furnace-gravity school the worst, while the window-fan occupied the middle position.

In contrast to the apparently clear-cut superiority of the furnace-gravity schools during the first year's study, the findings of the second year are contradictory and confused. This finding would seem to indicate that, in so far as the incidence of respiratory illness is concerned, more evidence is necessary before it is possible to say that one of the types of ventilation under investigation is superior to another.

DISCUSSION

PROFESSOR C.-E. A. WINSLOW, of Yale University, presented for consideration the following summary of the results obtained in 8 studies in 6 different cities:

ABSENCES DUE TO RESPIRATORY ILLNESS
Per 1,000 Pupil Sessions

Place	Year	Fan Supply	Unit Ventilation	Furnace	Window-Fan	Window-Gravity
New York	1915–16	14				10
New York	1916–17	13				11
New Haven	1926–27	30	32			18
Cleveland	1927–28	21				20
Syracuse	1926–27	30				
Syracuse	1927–28	22		18	24	
Chicago, W	1927–28	39		21		24
Chicago, N	1927–28	41		40		18

RESPIRATORY ILLNESS IN ATTENDANCE

Per 1,000 Pupil Sessions

Place	Year	Fan Supply	Unit Ventilation	Furnace	Window-Fan	Window-Gravity
New York	1915–16	76				22
New York	1916–17	98				44
New Haven	1926–27	22	61			31
Cleveland	1927–28	109				45
Syracuse	1926–27	126		70		
Syracuse	1927–28	27		42	25	

Despite the many inaccuracies involved in respiratory disease records, Professor Winslow believed that the picture presented by the table is a striking and convincing one. Absences due to respiratory illness show, in every one of the 6 instances, an excess in fan ventilated rooms, as compared with rooms ventilated by the window-gravity method, and in 3 cases out of 4 this is also true of respiratory illness in attendance. This latter factor is a highly inaccurate one, subject to great variation according to the personal equation of the teacher or the nurse who makes the observations. On the whole, however, the conclusion can hardly be resisted that respiratory disease in window-gravity ventilated rooms is only two-thirds as great as in fan ventilated rooms. Unit ventilation, furnace heating, and window supply with fan exhaust, closely resemble fan supply in their results.

The theoretical explanation of these facts is however exceedingly difficult. The New York Commission on Ventilation originally believed that fan rooms were prejudicial on account of overheating, but in New Haven and Chicago the fan rooms were cooler than the window rooms, and yet showed a very marked excess of respiratory disease. Nor can differences in relative humidity be invoked to explain the observed phenomenon. There remain, as the two most probable hypotheses, the effects of local drafts, or some as yet mysterious influence upon the electrical condition of the atmosphere incident to passing over highly heated surfaces.

Meanwhile, Professor Winslow pointed out that, even though we do not understand the fundamental physiological processes involved, we have apparently ample ground for preferring window ventilation, with an air change of some 10 cubic feet per minute, to fan ventilation with a larger flow of warmer air. There is no other means, hygienic or bacteriological, by which it is possible to reduce by one-third the incidence of infections of the upper respiratory tract, yet this remarkable result can apparently be accomplished by the substitution of one type of schoolroom ventilation for another.

Chlorination as a Factor of Safety in Shellfish Production*

WILLIAM FIRTH WELLS, FELLOW A. P. H. A.

Biological Engineer, North Atlantic Oyster Farms, Inc., West Sayville, N. Y.

FROM the Atlantic Seaboard of the United States come four-fifths of the world's production of oysters. Wholesale condemnation of these growing areas should become a public health measure of the last resort, after all the possibilities of conservation by public health engineering methods have been exhausted. Elimination of pollution is the ideal solution, but as in the protection of public drinking water supplies, prevention has not kept pace with increased pollution, and as by analogy we find in fact many valuable areas which can be conserved only through safety factors applied to the product.

Extensive studies of shellfish conducted over a long period of years have discovered biological and sanitary principles which enable us to control, under artificial conditions, the functions essential to their self purification. The transitory contamination for which oysters have been held responsible is not a true infection of the oyster but a bacterial accumulation in the healthy act of feeding.

Without attempting to describe the intricate mechanism of an oyster's gill, whereby in the combined process of breathing and feeding it filters daily many gallons of water to derive therefrom the minute drifting microscopic life and matter which constitutes its food, it is sufficient to a working understanding of the operation to state that the entire inner surface exposed to any contamination from the water is coated with a continuously moving mucus layer which carries along the agglutinated particles by ciliary action. This layer, constantly renewed by the secretion of sterile mucus from within, resembles in action a belt conveyor. Originating in the gill or incurrent water chamber, it travels crosswise to the current from which the food is strained, slowly forward through the funnel-shaped mouth, enters the sack-like stomach cavity, passes through the short gut reaching the cloacal or gill effluent chamber, and is ejected some five hours after entering the shells.

---

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

Bacterial contamination reaching the tissue surfaces through the feeding function is therefore by that same function progressing toward elimination. The significant fact in considering means for improving the sanitary quality of shellfish lies in the rapidity with which such matters are removed. Within a few hours the normal transit has been accomplished, and the bulk of accumulated material has been discharged in concrete masses from the animal. There remains but the problems of permitting or stimulating the natural bacterial elimination, while at the same time safeguarding the shellfish from recontamination.

It was further discovered that shellfish close tightly in the presence of considerable excess of free chlorine, thus protecting the interior tissues from its effects, but permitting the sterilization of everything exterior to the shells, and secondly, that the chlorine soon becomes neutralized, permitting the shellfish in pure salt water to eliminate rapidly by their natural functions all interior contaminating materials accumulated on the tissue surfaces.

Numerous experiments involving these principles, conducted since 1914, not only in this country but in England and France, have demonstrated the rapid reduction in bacterial contamination. A commercial plant for the cleansing of mussels has been in successful operation in England since 1916, and in New York State seven plants either for purifying oysters, or safeguarding the product during the conditioning operation have been constructed since 1922, treating some 250,000 bushels a year. As a result of promising studies by the Massachusetts State Department of Health, a plant for purifying soft clams is being installed, and suggestive results are reported in Rhode Island on the treatment of hard clams.

The action of New York State against the conditioning of oysters for the market in waters exposed to more or less direct local contamination, unless such waters are treated to a degree satisfactory to the Commissioner of Health, brought into prominence another aspect of the process. It has been the practice of several growers to store oysters in floats for a period sufficient to permit them to eliminate the food materials accumulated within their digestive tracts and on other tissue surfaces. Such a conditioning operation appears to enable long shipments in better condition and at the same time bring them clean to the table; and the use of chlorinated water prevents danger of recontamination after harvesting.

If the operation is carried out in accordance with the purification principles outlined, it not only secures the prevention of recontamination but to a high degree removes possible contamination from han-

dling. It constitutes therefore a factor of safety added to all oysters. Increasing experience continues to add new evidence that the greater danger does not lie in the growing area. Where the primary object is not to purify oysters from uncertified beds, but to eliminate chance contamination in the processes of preparation for the market, there is a striking analogy to the pasteurization of milk which may be sterile at the source but subject to contamination before it reaches the consumer.

The largest plant is capable of treating over 1,000 bushels of oysters a day in twelve shallow basins. Each basin is 11 by 22 feet and 2 feet deep. The oysters are supported by wooden racks which can be lifted to permit cleaning of the deposits which accumulate beneath. The salt water is pumped directly from the bay through a 200-foot suction line, and after chlorination is delivered 150 feet further into the basins. A hose stream of 150 gallons a minute permits the flushing of loose dirt from the oysters before closing the basins. Raised beveled edges insure drainage away from the basins, and the continual flushing of the concrete walks with chlorine water reduces to a minimum any chance of recontamination. This is further insured by maintaining an excess of chlorine in the basins in which oysters are being handled and throughout the working day changes of water containing several parts per million are frequently made. After the men have left the plant in the evening the water is drawn and refilling goes on with just sufficient chlorine to insure sterilization of the water without interfering with the functioning of the oysters. Before the men come on in the morning the basins are again emptied and refilled with stronger chlorine dosage again.

This plant has kept a bacteriological record of operation, and we are enabled to present the following statement of a year's results through the courtesy of the Bluepoints Company, Inc. Table I is a summary of a whole season's scores, classed according to the period of treatment, and shows the number and percentage of samples giving scores above 50, 5 and 0.5. There is a distinct decline in the percent-

TABLE I

RELATION BETWEEN SCORE AND TIME TREATED

Sept., 1926 to May, 1927

Hours Treated	No. Samples	Per Cent Scores Above 0.5	5	50
0	68	89.7	63.3	42.7
0 to 6	123	76.5	44.7	17.9
6 to 12	97	69.1	29.9	6.2
12 to 24	96	59.4	17.7	2.1
24 to 120	96	56.2	19.8	1.0

age of samples exceeding these scores as the period of treatment increases up to 24 hours. Beyond this period the change is not so pronounced, which suggests that a still slight recontamination tends on the average to maintain the score in the vicinity of this minimum value. While definite conclusions can be drawn from this table of percentages, a clearer index of bacterial reduction can be derived from a study of the distributions of samples by the statistical method applied in Figure I, where these values have been plotted on the basis of normal probability. The test of fitness to such treatment is given by the degree to which three points of each series fall on a straight line, which would be the case with perfect chance variation. It may be seen that by this test the closeness is quite sufficient to draw the conclusions which follow.

It is obvious that, in any case of chance distribution of bacteriological results, considerable variation exists, and isolated values both higher and lower are obtained from a product whether good or bad. The proportion of samples, however, which give a high or low value furnishes a measure of quality, and we have chosen the median as that

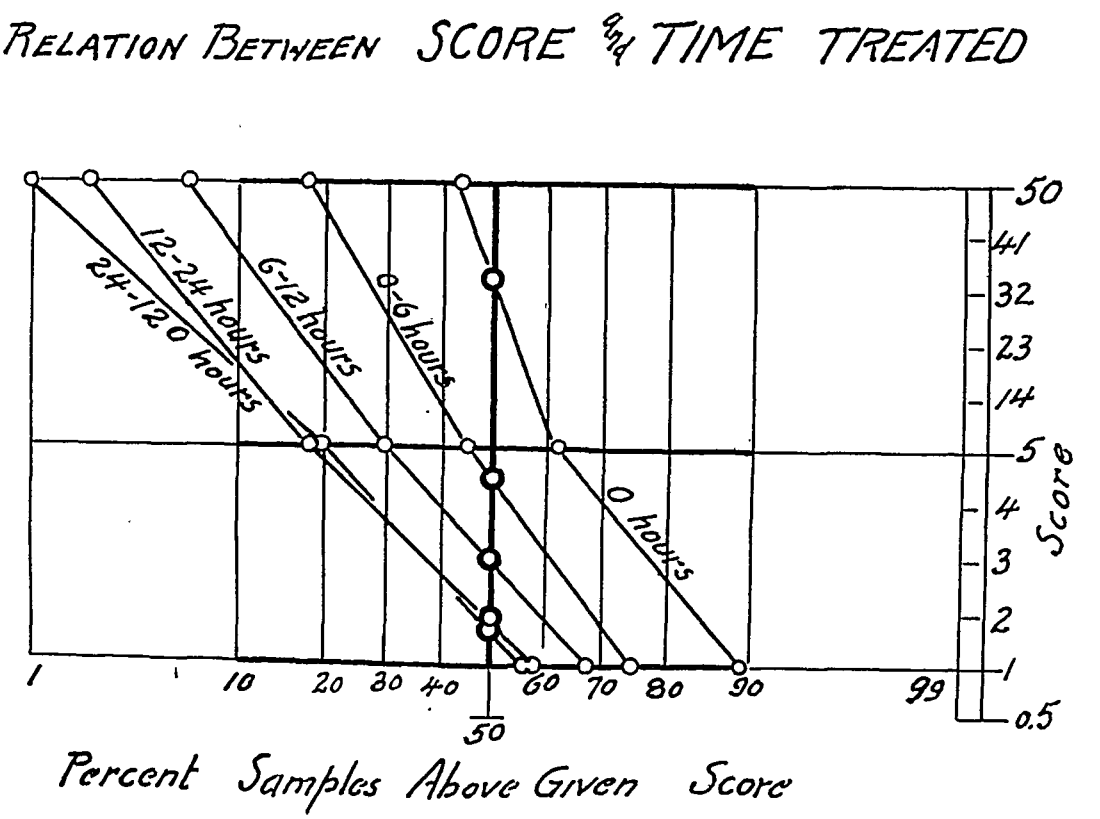

FIGURE I

Graphical determination of median score, from distribution of determined percentages of samples of oysters above given scores, plotted on Hazen's logarithmic probability paper.

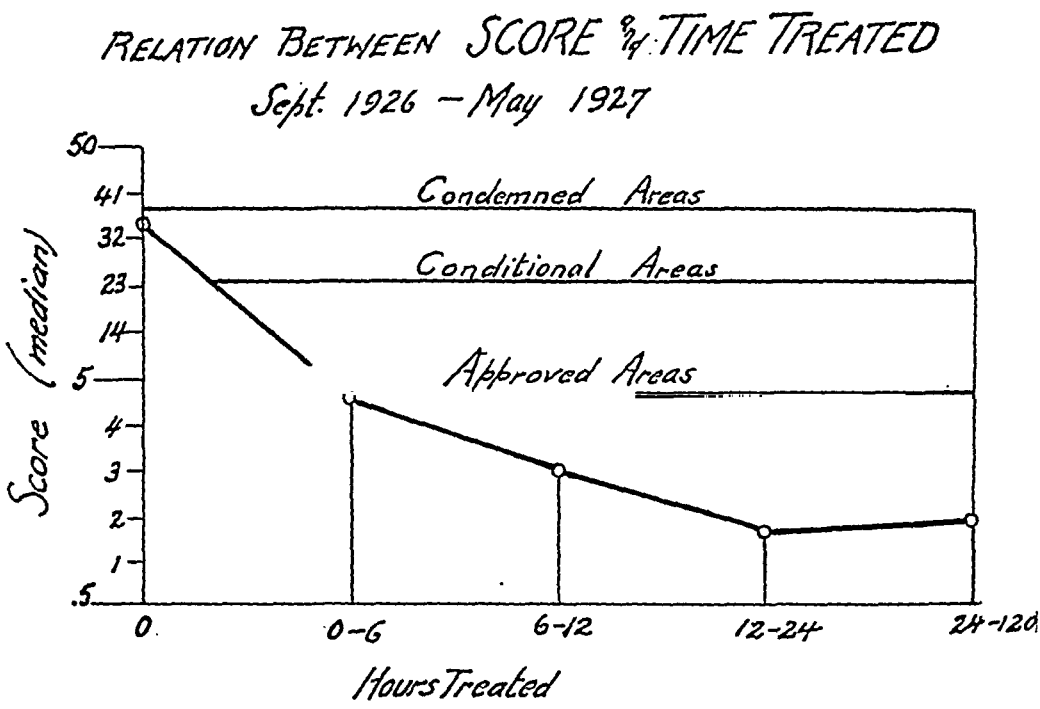

FIGURE II

Comparison of median annual scores of oysters, treated different periods in chlorinated sea-water, with median scores of oysters from classified grounds.

proportion which gives the most stable and accurate index of each series. In other words, we aim to discover that score which half the results would pass, and half would not. Incidentally the steepness of line indicates the degree to which the results vary from this value, and it may be observed that the initial results from a steeper line, which gets progressively flatter as the purification continues. This means that the treated oysters give a more consistent and uniform product than that started with, which should be credited as an advantage of the process beyond the mere lowering of the median score itself. Each heavy circle then includes a point representing the median score for each series. These have been transferred to Figure 11, which illustrates graphically the improvement in the oysters as they pass through the basins. The overall reduction in this score for the season after 24 hours' treatment is approximately 93 per cent.

TABLE II

SCORES FROM CLASSIFIED GROUNDS NARRAGANSETT BAY

(Averages of group percentages for 0–5–10–15° C.)

Area Class	No. Samples	Per Cent Scores Above 5	50
Approved	577	43.2	13.6
Conditioned	888	67.5	27.7
Condemned	638	83.7	35.5

The results of this practical performance may be interpreted by comparison with those from grounds classified according to the sanitary survey. The data collected by the State of Rhode Island during the years 1910–1915 give on Table II the values for three classes of grounds. They show on Figure II the striking similarity between the results from approved ground with those obtained by commercial treatment of oysters with results approaching those from grounds that have been condemned. From conditional grounds a wide margin of safety is provided. This margin will expand with the increased efficiency, through improved equipment and careful operation, represented by experimental results.

With liberal allowance therefore for all the actual and imaginary limitations which have been argued against purification processes, these results conclusively demonstrate the dependability of chlorination as a factor of safety, and show a wide and real margin of safety for oysters from conditional areas treated by the method as judged by its past commercial performance, and promise an increased margin of safety through improvements which inevitably result from continued practical operation. The sanitary quality of the resulting product under these conditions should represent a degree of safety equal and even exceeding that relied upon in oysters from approved grounds. Similar conclusions are reached by epidemiological evidence, which in America has so far failed to detect danger from the growing beds. The pollution load as so determined would, even with a Scotch verdict, be outweighed by any measurable reduction of infection risk, which need not exceed the status of a factor of safety.

CONCLUSION

The annual results of a large commercial plant show, without anticipation of improvement in efficiency indicated by experiments now in progress, that the method of treating oysters in chlorinated sea water is sufficiently well established at the present time to warrant a definite statement of its underlying principles, its achievement in practical operation, the field of its usefulness to the shellfish industry and the security it offers to public health.

DISCUSSION

GEORGE W. FULLER, FELLOW A. P. H. A.
New York, N. Y.

MR. WELLS' paper is a conservative and lucid expression of the present status of the shellfish industry in relation to its public health aspects. With the exception of milk none of our raw food supplies has been subject to the same degree of hazard between point of origin and the consumer as has shellfish. It is inevitable therefore that with so important a food supply, methods should be found to eliminate to a large extent the hazards and to create a feeling of greater confidence on the part of the consuming public than has previously existed.

It is creditable to the shellfish industry that it has had the vision to tackle its problems on a scientific basis and that it has also had the courage to put into practice a unique sterilizing method based both on the efficacy of chlorine and the physiology of the shellfish.

So far as has yet been brought out the chlorination treatment has reasonably met expectations and improved the score without impairing in any way the market value and edibility of the product. It is to be assumed that better results will be obtained as experience becomes available from plants now in operation or under construction.

A more or less general adoption of the chlorination method involves two main considerations, as has been indicated by Mr. Wells. First, is the improvement of the score and the establishing of a substantial safety factor for shellfish now taken from approved areas beyond polluting influences. The advantage of the highest feasible safety factor will be readily conceded by both the producer and the consumer.

The second consideration involves the proposal to make use of areas ecologically suitable for shellfish culture but subject to a degree of pollution which would make their use questionable in the absence of some such sterilizing treatment as has been proposed for overcoming pollutional hazards. It is quite logical to assume that present growing areas will be extended in this manner as confidence becomes established in the sterilizing method. Steps in this direction must be made cautiously however, because the safeguards depend not only upon soundness of the method but upon the kind of plant equipment employed and the adequate character and performance of the operating personnel.

The first water filtration plants and first milk pasteurization plants did not closely approach in reliability of performance the later ones, nor were the operators of these plants so well trained and equipped as those who came after them.

A factor of no little consequence to the shellfish industry is the development of public opinion so that sewage and other wastes of seashore and related communities will be taken care of satisfactorily. The restriction of the present shellfish areas is due largely to inadequacy of municipal sanitation. Such a situation is susceptible of correction if public opinion can be brought suitably to its support. Improved methods of safeguarding shellfish are no more excuse for slackening sewage treatment than is the construction of a modern filtration plant an excuse for substantial pollution of the raw water supply. Neither does pasteurization give a license to insanitary handling of milk.

The standing of chlorination as applied to shellfish depends largely upon the results obtained with the method in the hands of various workers and the relation of such results to conditions where there is substantial pollution.

FRED O. TONNEY, M. D., FELLOW A. P. H. A.

Department of Health, Chicago, Ill.

THE possible usefulness of the standard method of scoring oysters for *B. coli*, especially in so far as it may be applied to the control of the market product, is materially curtailed by the time required to obtain a final confirmed score on a given sample. A new method has been recently tried out in our laboratory, by which fuller information on the coli aerogenes content of oysters may be obtained in a shorter time.

Mr. Noble of our research staff has been experimenting with the application to oyster scoring of a new cyanide citrate pour plate method originally designed for water analysis.

The most interesting and striking feature of the findings by the new procedure is the indication that the *B. coli* score of oysters, as they reach our market, is principally a *B. aerogenes* score rather than a *B. coli* score. The significance of this finding at present is, of course, debatable, yet I must confess that it gave us a sense of relief to know that the high scores we have encountered were not usually due to the definite fecal type of organism.

R. E. NOBLE

Department of Health, Chicago, Ill.

AT this time we are prepared to state only approximate but interesting figures. We have found that in at least 90 per cent of positive samples the aerogenes types predominated. In these samples the ratio of aerogenes to coli colonies was usually very high and coli types were generally absent. Plate scores of total coli-aerogenes organisms, determined in a manner corresponding to the standard score, usually equalled or exceeded the latter. Plate counts may be less, equal to or greater than the standard score for a given volume of sample which, we believe, is explainable in terms of dilution. For example: a plate count from a 1 c.c. inoculation may show a count of 60 while the 0.1 c.c. and 0.01 c.c. portions in fermentation tubes are positive. Tentatively the conclusion is suggested that this plate method is suitable for oyster analysis and may be used with considerable saving of time in arriving at a confirmed *B. coli* score.

CAN PREVENTION GO TOO FAR?

CONTAGIOUS diseases can be prevented in two ways—complete isolation, which was attempted by our forefathers with greater success than is possible at present; and immunization, which may be acquired by what we call natural methods or by vaccination. The great success of vaccination against smallpox, and the methods introduced by Wright, have led to the tremendous use of artificial immunization by means of attenuated or killed bacteria or their products.

One may well ask if we have not gone too far in some respects, and if we have not made a mistake in trying to do away with nature's methods of producing immunity. As regards passive immunity, this question is of especial importance, since it is of short duration, and it is well known that when a contagious disease invades virgin territory, it rages with unusual violence. Where an active immunity can be produced by a vaccine, which is comparable to that following an attack of the disease under what may be called natural conditions, the work of man is all to the good.

Even in measles, which is generally regarded as 100 per cent infective, several observers have shown that in epidemics in regions where the disease is seen year after year, the history of previous attacks does not account for all who escape infection. The same statement may be made in regard to influenza, which is also highly contagious. The apparent immunity of those who escape such infections is explained on the ground that repeated small doses of the causative germ, not enough to produce symptoms recognizable either by the patient or by the physician, have produced a strong and lasting immunity. In certain other diseases which are not so highly infectious, such as diphtheria, infantile paralysis and meningitis, the same thing has been observed and fairly well proved.

It is well recognized that the germs of the acute diseases which we most dread are taken in through the upper respiratory tract and given out through the same channels. The droplet infection of Flügge has come to be recognized as of prime importance. Experiments have taught us how far germs can be carried by sneezing and coughing, and the conditions which influence the time they may remain suspended in the atmosphere.

Those responsible for the health in schools have especial reason to consider this mode of infection. In a somewhat loose method, it has been held that the ordinary contact during class periods of one hour is not sufficient time for infection to take place, though occasionally we have had cause to doubt the correctness of this claim. Observations in schools having both resident and day pupils have shown that during outbreaks of diphtheria and scarlet fever the residents were largely infected, while the day pupils remained completely free. The only discernible difference between the two was that the former slept together in dormitories, while the latter slept in separate homes.

Such facts have led Dudley to conclude that under ordinary conditions contact in classrooms for one and one-half hours, as well as the shorter periods on the playgrounds, were not sufficient to produce symptomatic infection. He has also observed that on naval vessels where overcrowding is present, but where ventilation is good, there is a remarkable freedom from contact infections. In the Navy, however, the men have gone through a period of training on shore which has resulted in a certain number of cases of disease and the apparent immunization of the majority.

In certain diseases the droplets are expelled to greater distances than others, owing to the explosive character of their projection. In meningitis, for example, separating the beds by 2½ to 3 feet has been shown to be sufficient to prevent infection; while in such diseases as common colds, influenza and diphtheria, the distance should be considerably greater—the further apart, the better. The separation in linear distance between the faces of individuals is of much more importance than the number of cubic feet of air space per person.

These and other considerations along the same lines have led certain epidemiologists, especially Dudley, to the conclusion that it is inadvisable to reduce too far droplet infection and the immunization produced by it. "Preventive Medicine deals with the herd, not with the individual." Recognizing the apparent cold-bloodedness of the view that individuals must suffer for the benefit of the many, Dudley makes the plain statement that in his own work he would be loath to do away with droplet infection from the naval training establishments

where young boys are converted into seasoned men by adaptation to the bacterial environment with which they must come into contact in their calling. The same reasoning may be applied, to a certain extent at least, to schools.

Many of the ideas expressed are not new, but Surgeon-Commander Dudley[1] has assembled them, with a number of corroborative facts, in a dissertation marked by originality as well as careful reasoning. Doubtless some will consider his ideas revolutionary, but we can commend them to the thoughtful consideration of all who are interested in this most important problem.

THE CALMETTE–GUÉRIN VACCINE

ATTEMPTS at vaccination against tuberculosis are not new, but all of them up to the present have been failures, though in laboratories certain experiments have had definitely successful results, among which we may mention those in this country by Pearson and Gilliland, at the University of Pennsylvania. In practice, however, we know of no method, either in animals or in man, which has been generally successful, though the laboratory work referred to has been sufficient to keep us hoping and to make us believe that someone will solve the problem in the not far distant future.

For a number of years we have followed eagerly the experiments of Calmette and Guérin, who succeeded in reducing the virulence of a mammalian tubercle bacillus through more than 20 years of cultivation upon a medium containing bile. After 4 years of such cultivation, it had lost its virulence for cattle, and after 13 for all experimental animals, though inoculated animals would react to the tuberculin test, and the germ itself would produce tuberculin. The ability and scientific honesty of Calmette, with his persistence and experience, have given unusual interest to his reports, the most recent and extensive of which are found in his book,[1] published in 1927, and in the current volume of the *Annals of the Pasteur Institute*.[2]

As far as the vaccination of animals goes, we have two recent and authoritative reports. The first[3] gives a series of experiments with guinea pigs. When the infecting dose was reduced to its lowest effective limit, the vaccinated animals were shown to live longer than the unvaccinated, and 6 of the vaccinated, when killed 20 weeks after the death of the last unvaccinated animal, were found to be free from tuberculosis. The authors feel justified in believing that guinea pigs may be completely protected against minimum doses of virulent

tubercle bacilli by means of BCG. Experiments upon guinea pigs, rabbits and young calves at the Research Laboratories of the Department of Agriculture of Canada[4] do not give such favorable results. In a pathogenicity test of BCG made on 134 guinea pigs, 92 were without a trace of tuberculosis when killed, while 30 showed infection, which in some cases appeared active and in others arrested or undergoing resorption. In the early experiments, 6 died of tuberculosis. The authors concluded that the vaccine could not be considered free of pathogenic power, and further showed that the virulence could be exalted by serial passage through guinea pigs; results which are in serious disagreement are those reported by Calmette, Guérin and others. The same workers found that young calves which after vaccination were exposed to natural infection by living with tuberculin reacting cows showed no greater resistance than the controls.

The authors consider that vaccination with BCG is still in the experimental stage, and that the claims made for its harmlessness are open to question.

In 1927, Calmette made an important modification in his vaccination of calves; namely, isolating them from possible infection for 30 days after vaccination, which indicates that his former procedure had not been entirely satisfactory.

These experiments have a direct bearing on the use of BCG for the protection of children. Calmette and his coworkers report on 3,808 children[2] and compare the deaths among these—3.1 per cent—with the general rate of mortality for the first year of life in France for 1922, which was 8.5 per cent. This report has been severely criticised. One is almost forced to believe that the favorable reports of the authors show an undue degree of optimism.

The most that we feel justified in saying is that the whole matter is in the experimental stage, but is in the hands of competent and experienced observers. It may be true, as some claim, that the use of BCG carries danger of infection to the child. Especially in view of the dissociation into two types, one virulent for guinea pigs and the other not, demonstrated by Petroff,[5] we are obliged to hold that the safety of the procedure has not been proved, and for the present must recommend caution in the use of the vaccine while hoping for the best.

A REPORT WITH REAL MEAT

THE recently issued report of the Malaria Commission,[1] Health Section, League of Nations, is notable not only for the sound advice on its special problem, but also for the clear enunciation of fundamental principles applicable to all types of public health work. The commission considers it inadvisable to utilize "all available methods of control in the same locality at the same time," preferring to employ first those methods which can be raised above the standard called "minimum effective degree of perfection," this depending upon the means available. Each locality should be studied and methods of control adapted to the region put in force, since measures which are successful in one area may fail in others, owing to different conditions.

Malariologists have widely divergent views which are vigorously defended. Each proposed method varies according to its necessities, efficacy and cost, these in turn depending upon social and economic conditions. These differences of opinion exist in spite of the fact that the basic principles of malarial control are well understood and have been proved efficient in practice. Malaria flees before scientific agriculture. "Integral bonification," a term obtained from Italy, meaning the complete reclamation of land for agricultural purposes by any method or any combination of methods, requires a long time for accomplishment. While this is the ultimate object of antimalarial work, the commission recognizes that the first step must be early diagnosis and treatment of infected persons.

Among other fundamentals, the report points out that each case requires observation and analysis of the factors involved, but "The principal factor in the success of any method is the energy of the hygienist employing it."

Hygiene has often suffered from an excess of zeal on the part of its friends combined with a deficiency of knowledge; for instance, the wholesale slaughtering of cattle on the tuberculin test, the latter often carried out under conditions which precluded the possibility of reliable results. Vaccination against smallpox has suffered at the hands of its over enthusiastic advocates who did not know, or neglected to recognize, the fact that the duration of immunity is variable, so that vaccination with re-vaccination must be taught as well as practiced. Examples might be multiplied, but these will suffice.

Every popular movement attracts undesirable elements to its support, some carried away by an excess of zeal, but some who wish to ride on the crest of the wave for financial or other reasons. In perhaps no other profession is the old saying concerning a little learning being a dangerous thing more true than in public health. Signs are

not lacking of a reaction against the fallacious teaching and practices of underinformed enthusiasts. A letter on "Debunking Health Education"[2] illustrates this. So-called health education, as well as practices founded on "bunk," leads inevitably to the discredit of the efforts of those who are sincere as well as trained, the foundation of cults, and the putting on the market of various foods and preparations for which miraculous claims are made. The list of food fads alone would fill pages. We need only mention the war against white bread, raisins for iron, the alleged effects of constipation or of eating hot food in causing cancer, and so on *ad nauseam*.

As long as the world goes round, a regular crop of fakirs and "suckers" will be produced, each to supply the demand for the other. Well may we pray: "O Lord, make all the bad men fools," since fools seldom attract a large following. Unfortunately most "fakirs" are smart, and know how to play upon human nature. It takes the philosophy of an Oliver Wendell Holmes or a William Osler to accept conditions with equanimity.

We dislike the rôle of preacher, but it seems clear that we must continue our efforts for higher standards of education. For those desiring to engage in public health work or public health teaching, a minimum standard of education should be required, and also a license similar to that required for physicians or lawyers. There is no more reason why the degree of Doctor of Public Health should be sufficient to turn a person loose on the public than there is for the degree of Doctor of Medicine to give the right to practice. All physicians must be licensed after having obtained their degrees, irrespective of the standing of the school from which they graduate. This view is perhaps Utopian, but our aim must be high, even though for a time we may fail in accomplishment.

THE GOVERNMENT AND THE PUBLIC HEALTH

THE Executive Council of the American Medical Editors' Association has adopted a resolution declaring the sentiment of the association to be that there should be a medical officer in the Cabinet of the President of the United States. The work of such an officer would be to "look after the interests of the medical profession, and to represent the public health of the nation."

We believe that the medical profession is a unit, in the opinion that there should be a department headed by a cabinet officer for the pur-

pose of directing the welfare of the nation in regard to public health. History is full of instances showing that good health is the greatest single asset which any nation can possess, and this has been recognized by statesmen for many years. All of us are familiar with the statement of Disraeli, "The Public Health is the foundation on which reposes the happiness of the people and the power of a country. The care of the Public Health is the first duty of a statesman," and endorse it. Gladstone said: "In the health of the people lies the strength of the nation."

Nations which are at war recognize the practical bearing of such statements. The commanding general of an army demands that the sick report be made early each day, as he is compelled to know what effective force he can count upon. Strangely enough, there is no such report in times of peace, and we can only guess at the number of disabled and dependent persons in our nation. The most severe charge that can be made concerning this is the well known fact that a large percentage of the disablement is due to preventable and remediable conditions. This was clearly shown in the draft examination during the World War. England and Canada acted on what they learned during that period, and now have cabinet ministers in charge of national health.

If any business were conducted as inefficiently, in regard to bookkeeping as well as practice, as its health matters are conducted by our country, it would go to the wall in a short time. If anything good can be said about war, it is that it has brought to the attention of the nation a condition of affairs which calls loudly for remedy. That conditions are not worse than they actually are is due to the numerous volunteer health organizations which have done, and are doing, such splendid work in various specialties, and which are arousing public opinion. We must also pay our sincerest tribute to the U. S. Public Health Service; but our national organization is such that it is hampered in functioning within the states.

Under the fear of an epidemic of yellow fever, we once undertook the experiment of a National Board of Health, but it was continued only 4 years, though some of its functions were then delegated to the U. S. Public Health Service.

The resolution of the American Medical Editors' Association seems to us to fall short of meeting the necessities of the case, though it is a step in the right direction. We have all watched the movement for the reorganization of the governmental departments in Washington, and are still hoping to see this come to full fruition. In any reorganization which is finally achieved, the health of the nation must take a prominent place.

Our Association has for 3 years endorsed the Parker Bill, which we believe comes much nearer to what is wanted by the people of the country, and what is needed, than merely having a medical officer in the Cabinet. It was passed by the Seventieth Congress, but vetoed by the President. At our recent meeting in Chicago a resolution was adopted urging Congress to pass the Bill over the veto.* It behooves all members of our Association to bear this in mind when Congress convenes, and to use all possible influence on their Representatives.

The great French philosopher Descartes said: "If ever the human race is raised to its highest practicable level, intellectually, morally and physically, the science of medicine will perform the service."

CONSTITUTION AND BY-LAWS, AND CONSTITUTION FOR SECTIONS, AMERICAN PUBLIC HEALTH ASSOCIATION

As Amended by the Governing Council at the Fifty-seventh Annual Meeting, Chicago, Ill., October 15–19, 1928

CONSTITUTION

ARTICLE I NAME

The name of this Association, incorporated under the laws of Massachusetts, is the American Public Health Association.

ARTICLE II OBJECT

The object of this Association is to protect and promote public and personal health.

ARTICLE III GOVERNING COUNCIL

A. *Composition:* There shall be a Governing Council consisting of:

1. The officers of the Association.

2. Thirty members of the Council, to be elected by and from the Fellowship of the Association, for three-year terms, one-third retiring each year. These members of the Council shall be nominated and elected as provided for in the By-laws.

If one of these members is elected a Section Chairman, Vice-Chairman, or Secretary, or appointed the representative of an Affiliated Society, a new Councilor to fill such vacancy shall be elected by the Governing Council.

3. The Chairman, Vice-Chairman and Secretary of each Section.

4. A representative to be appointed by each affiliated society to serve for one year. Such representative shall be at the time of his appointment a Fellow of the American Public Health Association.

5. The elective members of the Council of the Health Officers Section.

B. *Terms:* Terms of Councilors shall begin at the end of the annual meeting when elected, and shall terminate at the end of the annual meeting at expiration of term; provided that Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

C. *Reëlection:* After two consecutive terms, an elective Councilor shall be ineligible for reëlection to the Council during one Association year.

D. *The Officers* of the Association shall be the officers of the Council.

E. *Functions:* The functions of the Council shall be:

1. To establish policies for the Association and for the guidance of the Executive Board and the officers.

2. To establish Sections of the Association, to combine or discontinue them when necessary, to maintain coördination among them, and to formulate general rules governing the policies of the Sections.

3. To submit to the vote of the Association all resolutions which have received the approval of the Governing Council.

4. To elect Affiliated Societies, Fellows and Honorary Fellows as provided in the By-laws.

5. To elect the Executive Board and the officers of the Association.

6. To receive from the President, on behalf of the Executive Board, a report of the meetings, policies and work of the Executive Board; a report from the Executive Secretary concerning the administrative work of the year; and a report from the Treasurer concerning the finances of the Association.

F. *A Quorum* of the Council shall consist of ten Councilors.

G. *Meetings* of the Council shall be called by the Executive Secretary at the request of the President, or at the request in writing of any twelve Councilors. In the latter case, the call to meeting, issued at least twenty days in advance, shall state the purpose of the meeting.

ARTICLE IV OFFICERS

The officers of this Association shall be a President, three Vice-Presidents, an Executive Secretary, and a Treasurer. The officers, with the exception of the Executive Secretary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. Officers shall serve from the close of the annual meeting when elected, until the close of the next annual meeting, and until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained. The Executive Secretary shall be elected by and serve at the pleasure of the Executive Board.

ARTICLE V AMENDMENTS

This Constitution may be amended by a two-thirds vote of the Members of the Association present and voting at an annual meeting, provided that the specific amendment to be acted upon is published in the official publication of the Association not less than thirty days prior to the meeting, and provided further that the amendment has received the approval of the Governing Council.

BY-LAWS

ARTICLE I MEMBERSHIP AND DUES

A. There shall be a standing Committee of the Governing Council on Eligibility, consisting of one Fellow from each established Section to be appointed by the President, with terms of three years each, as equal a number as possible expiring each year, the terms of those first appointed to be determined by lot conducted by the Executive Board; this committee to perform such duties as may be specified herein, and such other duties as may be assigned to it from time to time by the Governing Council.

B. There shall be eight classes of constituents who may be elected from the United States, Canada, Mexico, Cuba, and such other countries as may be admitted to representation in the Association. This provision shall not apply to Honorary Fellows or Associate Members. The respective appellations, qualifications for election, and dues shall be as follows:

1. *Fellows:* Only professional health workers, who have been Members of the Association for at least two years, and of established professional standing (whether employed by public or private agencies or in independent private practice), shall be eligible for election as Fellows, provided that a Member shall be not less than thirty years old at the time the application for Fellowship is made, and provided, further, that the following persons shall be considered to have an established standing in the profession of public health, namely:

a. A person who has attained the degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, or other equivalent degree, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has attained an academic or professional degree involving training in public health, and who has been regularly engaged in public health work for four years, having rendered meritorious service in the public health profession, either as a health officer or in responsible charge of work in a state or municipal department of health or other official public health organization.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing equivalent to that required for Fellows under paragraphs "a" and "b."

d. A person regularly engaged in public health work for at least five years, who has given evidence of special proficiency in the service of an official or unofficial public health organization, and who has attained a professional standing equivalent to that required for Fellows under paragraphs "a" and "b."

e. A teacher of public health or one of its constituent sciences. As such he shall have attained distinction as an expounder of the principles of public health or its constituent sciences and he shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch of public health service, and who has attained a professional standing equivalent to that required for Fellows under paragraphs "a" and "b."

The application for Fellowship shall be made on an approved form and shall be sponsored by two Fellows of the Association who shall be Fellows of the Section with which affiliation is desired, provided, however, that when affiliation with a Section is not desired, the sponsors may be any two Fellows in good standing in the Association. Fellows without Section affiliation shall be known as unaffiliated Fellows.

When the application has been duly sponsored and otherwise completed, it shall be transmitted to the Executive Secretary of the Association, who will make note thereon of such knowledge as he may have concerning the standing of the applicant in the Association. The application shall be forwarded by the Executive Secretary to the Secretary of the Section in which affiliation is desired, for the approval of the Section Council, and when acted upon by the Section Council, it shall be returned to the Executive Secretary by the Secretary of the Section, after he has made endorsement on the application of the action of the Section Council. When the application is for unaffiliated Fellowship, the Executive Board of the Association shall act in place of the Section Council. When the application has been approved by a majority of the Sec-

tion Council or the Executive Board, as above provided, it shall be voted upon by the Governing Council, provided the name of the applicant shall have been officially published at least fifteen days in advance, and provided further that the application shall have been approved by the Committee on Eligibility.

A Fellow may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Fellows may become affiliated with a Section if approved by vote of a majority of the Council of the Section in which affiliation is desired.

The right to hold office or to serve as chairman of a committee in the Association shall be limited to the Fellows of the Association, whether Section Fellows or unaffiliated Fellows. The right to hold office or to serve as chairman of a committee in a Section shall, however, be limited to the respective Fellows in such Sections.

The dues of Fellows shall be $10.00 per year.

2. *Honorary Fellows:* Honorary Fellows may be elected by the Governing Council for distinguished service in public health. Honorary Fellowship shall not include voting power or payment of dues.

3. *Members:* Persons professionally engaged in public health work shall be eligible for election as active Members when sponsored by two Fellows of the Association. They may serve on committees, except as chairmen. Dues $5.00 per year. A Member may belong to only one Section but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Members may become affiliated with a Section if approved by vote of a majority of the Council of the Section in which affiliation is desired.

4. *Associate Members:* Persons interested in public health shall be eligible as Associate Members. They may serve on committees, except as chairmen. Dues $5.00 per year.

5. *Sustaining Members:* Individuals or corporations interested in public health may be elected to Sustaining Membership. Dues $50.00 or more per year.

6. *Affiliated Societies:* A state or provincial public health association or similar regional society including more or less than a state, primarily composed of professional public health workers and organized for the same general objects as the American Public Health Association, may be elected as an Affiliated Society, provided that not less than twenty of its active members and at least one-half of its active members are Members or Fellows of the American Public Health Association. Not more than one such society shall be admitted from the same area.

A society applying for affiliation shall submit a copy of its constitution and by-laws, its last annual budget, a roster of its members and such other evidences of its qualifications as it may desire to submit.

The Committee on Eligibility shall consider all applications for affiliation and report its recommendations to the Governing Council.

The annual dues of Affiliated Societies shall be one per cent of their gross annual income, the minimum dues per society being $10.00 per year.

Each Fellow, Member, Associate Member, and Affiliated Member of the American Public Health Association shall be a member of the Affiliated Society to which he is eligible and, after January 1, 1927, no person eligible for election to an Affiliated Society shall be admitted to Membership, Associate Membership or Affiliated Membership in the American Public Health Association unless such person has qualified or at the same time qualifies as a member of an Affiliated Society.

For every Fellow, Member, Associate Member or Affiliated Member paying annual dues to the American Public Health Association, the American Public Health Association shall remit to the Affiliated Society of which such person is a member the sum of $1.00 per annum.

7. *Affiliated Members:* This class of membership shall include all active (namely professional) members of Affiliated Societies, and in areas where no Affiliated Societies exist such other professional sanitarians as may be elected to this grade. Dues $1.00 per year.

8. *Life Members:* Upon the recommendation of the Committee on Eligibility any individual member of the Association may be elected a member for life. Election to this grade shall not affect the privileges held by such individual in his previous grade of membership. The dues for Life Members shall be $100.00, payable within one year after election, and this payment by such member shall exempt him from any further dues.

C. *Election:* The election of Fellows (see A1 above), Honorary Fellows and Affiliated Societies shall be by the Governing Council.

The election of Members, Associate Members, Life Members, and Sustaining Members shall be by a committee appointed by the Executive Board.

Three-fourths of the votes cast shall be requisite for election.

Upon the recommendation of the Committee on Eligibility the Governing Council may discontinue the Membership, Fellowship or

affiliation of any constituent. Three-fourths of the votes cast shall be necessary for such action.

D. *Dues:* Dues are payable annually in advance. All constituents paying dues shall be entitled to receive the AMERICAN JOURNAL OF PUBLIC HEALTH and, or, such other publications as may be designated by the Executive Board, which shall determine the proportion of dues to be devoted to this purpose.

Constituents of any class whose dues are unpaid for six months or more shall be considered not in good standing. Constituents not in good standing shall not be entitled to vote, hold office or enjoy other privileges or powers of membership. Good standing may be resumed upon the payment of all arrears and dues in advance for one year, provided, however, the lapsed period is not greater than one year. The Executive Secretary shall notify by registered mail all constituents who have been in arrears for a period of eleven months. The names of constituents in any class whose dues remain unpaid for one year or more shall be presented to the Executive Board which shall order the names of such constituents stricken from the Membership roll, provided, however, such constituents have been duly notified as hereinbefore provided in this paragraph. Constituents whose names have been stricken from the rolls in this manner may be again admitted in the manner provided for the election of new constituents in the class for which they make application provided such person or organization complies with the eligibility requirements at the time the new application is made.

ARTICLE II GOVERNING COUNCIL

At least four months before the Annual Meeting the President with the approval of the Executive Board shall name a Nominating Committee of not less than three Fellows, no two of whom shall be from the same Section of the Association or the same state. This committee shall present to the Executive Secretary at least two months before the next Annual Meeting the names of at least twenty and not more than thirty Fellows of the Association selected with due regard to geographical and Membership considerations as nominees for the Governing Council. The Executive Secretary shall publish this list to the Membership. Upon the petition of twenty-five Fellows the Nominating Committee shall add the name of any Fellow to this list provided such petition is received fifteen days before the Annual Meeting. The time for closing the polls shall be determined each year by the Executive Board. The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting shall be declared elected. Should two or more candidates receive the same number of votes the Executive Board shall, when necessary, determine by written ballot the order of precedence.

ARTICLE III EXECUTIVE BOARD

A. *Composition:* There shall be an Executive Board of ten members elected by the Governing Council, six of whom shall be members of the Governing Council, and four of whom shall be the President, the retiring President, the Treasurer, and the Chairman of the Finance Committee.

B. *The Terms* of the President, the retiring President, the Treasurer, and the Chairman of the Finance Committee as Executive Board members shall be one year each, and the terms of the other members shall be two years each, expiring in rotation, three each year. These terms shall begin at the end of the annual meeting at which elected, and shall continue until the end of the annual meeting at expiration of term, provided that newly elected members of the Board shall have the right to attend meetings as soon as elected, and shall have no vote until installed.

C. *Reëlection:* After two consecutive terms a member of the Executive Board shall be ineligible for reëlection during one Association year. This provision shall not apply to an officer of the Association.

D. *The Officers* of the Association shall be the officers of the Executive Board.

E. *Duties:* The duties of the Executive Board shall be:

1. To direct the administrative work of the Association.

2. To act as trustee of its properties.

3. To procure funds and to authorize budgets for the Association work.

4. In general to carry out the policies of the Governing Council between meetings of the latter.

F. *A Quorum* of the Executive Board shall consist of four members.

ARTICLE IV OFFICERS

The officers elected by the Governing Council shall be nominated from the floor.

ARTICLE V MEETINGS OF THE ASSOCIATION

There shall be at least one annual meeting of the Association, held at a place to be selected by the Governing Council. Special meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association.

There shall be a Central Program Committee composed of the Secretaries of the

several Sections of the Association and the President and Executive Secretary of the Association. The scientific program of meetings of the Association shall be prepared under the direction of the Central Program Committee.

ARTICLE VI SECTIONS

Sections shall elect their own officers. They shall conduct sessions in coöperation with and under the supervision of the Executive Board. The Constitution and By-laws of Sections and amendments thereto shall be submitted for the approval of the Governing Council, and shall be valid only after such approval.

ARTICLE VII PUBLICATIONS

All publications of the Association and of its Sections shall be issued under the direction of the Executive Board. The Executive Board shall appoint a Managing Editor of the official journal, who may also be the Executive Secretary of the Association. The Executive Secretary shall, with the approval of the Executive Board, appoint an Editorial Board of not less than five members, to serve at the pleasure of the Executive Board. All papers and reports for the annual meetings are to be accepted with the understanding that they shall be the property of the Association for publication, unless this right is waived by the Managing Editor.

ARTICLE VIII STANDARDS

There shall be a Council on Standards which shall be designated by the Executive Board. Any resolution, report or publication which undertakes to establish in the name of the Association or any of its Sections professional or technical standards, shall be submitted to the Council on Standards. The Council shall give notice by publication to the Membership of all proposed standards and report its approval or disapproval of such proposed standards to the Governing Council.

Proposed standards approved by a three-fourths vote of the Governing Councilors voting shall become official standards of the American Public Health Association.

ARTICLE IX FINANCES

The Executive Secretary shall receive and deposit to the account of the Treasurer all remittances sent to the Association. The Treasurer shall be custodian of investments of the Association and shall disburse funds in accordance with duly authorized vouchers. With the approval of the Executive Board he may establish a drawing account for the Executive Secretary. The Executive Secretary shall send each month to members of the Executive Board a financial summary of receipts and disbursements. Once each month, or oftener if called for, he shall also forward to the Treasurer and President an itemized statement of all expenditures. The Executive Secretary and the Treasurer shall be bonded at the expense of the Association in an amount to be determined by the Executive Board. The books of the Association shall be audited annually by certified public accountants, to be appointed by the Executive Board.

ARTICLE X COMMITTEES

Committees of the Association shall be authorized by the Governing Council or the Executive Board. The President shall appoint the members of such committees. Such appointments expire at the next annual meeting, unless otherwise specified.

ARTICLE XI AMENDMENTS

These By-laws may be amended by a majority vote of the total membership of the Governing Council during the annual meeting, provided that twenty-four hours prior written notice thereof has been given. The By-laws may further be amended by a two-thirds vote of those voting at any meeting of the Governing Council called for the purpose, provided that notice thereof shall have been given at least fifteen days prior to such meeting.

CONSTITUTION FOR SECTIONS

ARTICLE I NAME

The name of this body shall be the ..... Section of the American Public Health Association.

ARTICLE II SCOPE OR OBJECT

(To be stated briefly for each Section.)

ARTICLE III MEMBERSHIP

A. *Voting Power:* The right to hold office or to serve as the chairman of a committee shall be limited to Fellows of this Section who have been elected under the By-laws of the Association.

Members may participate in the scientific sessions of any Section and may affiliate with any one Section. They may serve on committees except as chairmen.

B. *Payment of Dues* in the Association is a prerequisite to Section Fellowship, and non-payment of dues shall invalidate Section Fellowship and Membership.

ARTICLE IV SECTION OFFICERS

A. *The Officers* of this Section shall be a

Chairman, a Vice-Chairman, and a Secretary. These three officers shall be the representatives of the Section to the Governing Council of the Association.

B. *Terms:* New terms begin and old terms expire at the end of annual meetings. After four consecutive years in any elective Section office, except that of Secretary, a member shall be ineligible to reëlection to that office during one Association year.

C. *The Chairman* shall preside at meetings of the Section and of the Section Council, and shall be Chairman of the Committee on Program, and of the Committee to advise on Publication of Papers in the AMERICAN JOURNAL OF PUBLIC HEALTH.

D. *The Vice-Chairman* shall preside at meetings of the Section and of the Council in the absence of the Chairman, and he shall be a member of the Section Council.

E. *The Secretary* of the Section shall keep the minutes, and other records of the Section and of the Section Council; and shall transmit to the Executive Secretary of the Association a copy of the minutes of both business and scientific sessions as soon as practicable thereafter. When unable to be present at meetings, he shall thoroughly instruct a substitute as far in advance of the meeting as possible.

The Secretary of the Section shall be ex-officio a member of all Section committees.

The Section Nominating Committee shall renominate capable Section Secretaries whenever practicable, in the interest of continuity in Section work and policies.

ARTICLE V NOMINATION AND ELECTION

A. *Nominating Committee:* The Section Chairman, with the advice of the Executive Committee of the Section, shall appoint a Committee on Nominations at least fifteen days before each annual meeting. The Section Secretary shall be a member of such Committee.

The Committee on Nominations shall present, not later than the second meeting of the Section, at each annual meeting of the Association a list of nominees for the Section offices, and for membership in the Section Council; provided that if the name of any Fellow be transmitted to the Section Secretary over the signature of ten Fellows of the Section at least fifteen days in advance of an annual meeting, the Nominating Committee shall add the name of such Fellows to its own list of nominees. No nominations shall be made from the floor of the meeting. Election shall be by the Fellows of the Section.

Should the Section Chairman fail to appoint a Committee on Nomination as above provided, such a committee shall be appointed for the Section by the President of the Association.

ARTICLE VI SECTION COUNCIL

A. *Composition:* There shall be a Section Council composed of the three officers and from three to six elective members, who shall be Fellows of the Section.

B. *The Terms* of elective Councilors shall be two years each and shall expire in rotation. Terms of Councilors shall begin immediately after the annual meeting when elected; provided that Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

C. *Duties:* The duties of the Section Council shall be:

1. To act in the capacity of a board of directors for the Section.

2. To supplement the Section in authorizing the appointment of committees by the Section Chairman, and to advise in the selection of personnel.

3. To act as a Committee on Resolutions for the Section.

4. To nominate Fellows for election under the By-laws of the Association.

5. To inform the Editor of the official Journal which papers and reports presented at Section meetings merit publication.

D. *Executive Committees:* Between annual meetings, the Section officers shall act as an Executive Committee of the Section Council.

E. *Meetings:* At least one meeting of the Council must be held at the annual meeting of the Section. Interim meetings may also be called by the Section Chairman.

F. *Attendance:* Absence from two consecutive annual meetings, or failure to answer two consecutive official communications on Section business requiring reply, shall be equivalent to resignation from the Council, subject to reinstatement by the Council if good cause is furnished.

ARTICLE VII SECTION COMMITTEES

A. *Authorization:* Committees of the Section may be authorized by the Section or by the Section Council.

B. *Appointment:* Appointment of committee personnel shall, unless otherwise specified, be by the Section Chairman with the advice of the Section Council.

C. *Reports:* All scientific reports, upon presentation to the Section, shall be referred by the Chairman to the Section Council, or to a special reference committee which shall report back to the Section. The Section shall then vote on each report whether or not to adopt. In case of failure of the Section to

take definite action before the end of the annual meeting, such duty shall devolve upon the Section Council.

ARTICLE VIII PROGRAMS

A. The programs of the Sections shall be prepared by the Section Secretary in accordance with the Constitution and By-laws of the Association and the rules and standards established by the Central Program Committee.

B. *All Section Papers* and reports shall automatically become the property of the Association for publication purposes, except as this right is waived by the Managing Editor.

ARTICLE IX AMENDMENTS

Amendments to this Constitution may be made only by the Governing Council of the Association, and in the same manner as the By-laws of the Association; provided that the Section may adopt By-laws not in conflict with this Constitution.

ASSOCIATION NEWS

A. P. H. A. REPRESENTATION INVITED TO PACIFIC SCIENCE CONGRESS

The A. P. H. A. has been asked to send delegates to the Fourth Pacific Science Congress at Batavia and Bandoeng, Java, May 16–25, 1929. This congress will be held under the auspices of the Netherlands Indies Pacific Research Committee, supported by the patronage of the Netherlands Indies Government.

The executive committee of the Fourth Congress has planned the organization of the Congress by four divisions including: Physical Sciences, Biological Sciences and Agricultural Sciences.

DR. GEIGER RAILROAD CONSULTANT

J. C. Geiger, M.D., associate professor of epidemiology, University of California Medical School, San Francisco, Calif., has been appointed through the university as epidemiologist and consultant in public health and hygiene for the Southern Pacific Railroad System. Dr. Geiger has recently made an investigation of tularemia along the railroad's lines in Nevada. He is a Fellow of the A. P. H. A. and is a member of the section council of the Food, Drugs and Nutrition Section of the Association.

DR. CLARENCE O. SAPPINGTON GOES WITH NATIONAL SAFETY COUNCIL

Clarence O. Sappington, M.D., a member of the A. P. H. A. and a frequent contributor to the AMERICAN JOURNAL OF PUBLIC HEALTH AND THE NATION'S HEALTH, has been appointed the first director of the newly created division of industrial health of the National Safety Council, Chicago, Ill.

MR. SHERE GOES TO COMMERCIAL FIRM

Lewis Shere, a member of the Public Health Engineering Section, and a frequent contributor to the JOURNAL, has been granted a year's leave of absence from the Chicago Health Department, where he has been director of the City Division of Dairy Products, to become Director of Research and Publicity of the Diversey Manufacturing Company, Chicago, Ill.

DR. PATTERSON ON STAFF OF JOHN HANCOCK LIFE INSURANCE COMPANY

Raymond S. Patterson, Ph.D., Fellow of the A. P. H. A., formerly with the New Jersey State Department of Health, has been appointed director of health education of the Life Conservation Service of the John Hancock Mutual

Life Insurance Company, Boston, Mass. Dr. Patterson is editor of the Selected Public Health Bibliography published monthly in the *American Journal of Public Health and The Nation's Health,* and has been active in the Public Health Education Section of the Association.

DR. DAVIS WITH ROSENWALD FUND

Michael M. Davis, Ph.D., a Fellow of the A. P. H. A., and chairman of the sub-committee on Organized Care of the Sick of the Committee on Administrative Practice of the Association, has been appointed to the executive staff of the Julius Rosenwald Fund as director for Medical Services. Although Dr. Davis will be permanently located in Chicago, he will continue his close cooperation with the Committee on Administrative Practice. Dr. Davis will direct the program which the Julius Rosenwald Fund is planning to undertake in improving the organized facilities for medical service to the average man of moderate means.

NEW MEMBERS

Alice C. Bagley, R.N., San Francisco, Calif., Assistant Superintendent of Nursing, Metropolitan Life Insurance Company

Charles W. Bergquist, Chicago, Ill., President Chicago Tuberculosis Institute

Shaoch'ing Hsipo Ch'uan, M.D., Tientsin, China, Health Commissioner (Assoc.)

Bertha C. Clow, M.S., Madison, Wis., Instructor and Research Worker in Home Economics Department, University of Wisconsin

Winifred Colvin, R.N., Chicago, Ill., Public Health Nursing

Mary T. Dowling, R.N., New York, N. Y., Industrial Nurse with Press Publishing Company

Neil S. Dungay, Ph.D., M.D., Northfield, Minn., Professor of Hygiene and Public Health and Director of Health Service, Carleton College

George Hay, M.D., Johnstown, Pa., Former Health Officer and City Physician

Jacob J. Hood, M.D., Cicero, Ill., Health Commissioner

Letta Jones, R.N., Chicago, Ill., Public Health Nursing

Henry F. Juengst, C.E., St. Joseph, Mo., Bacteriologist and Civil Engineer, St. Joseph Water Company

Stuart K. Knox, Montclair, N. J., Consulting Hydraulic and Sanitary Engineer

Carl J. Lauter, Washington, D. C., Chief Chemist, Washington, D. C., Water Supply

Charles H. Mayo, M.D., D.P.H., Rochester, Minn., Health Officer

Marion McKinney, B.A., M.S., White Plains, N. Y., Statistician, Health Department

Esther H. Oyhus, Chicago, Ill., Teacher of Oral Hygiene in Public Schools

Ivan C. Peterson, Chicago, Ill., Municipal Engineer

Margaret Reid, B.S., R.N., Indianapolis, Ind., Nursing Field Representative, National American Red Cross of Washington, D. C.

Alphonse M. Schwitalla, A.M., Ph.D., St. Louis, Mo., Dean, School of Medicine, St. Louis University

Roy Schneiter, M.S., Rouses Point, N. Y., Junior Bacteriologist, Food, Drug and Insecticide Adm., U. S. Department of Agriculture

T. B. Sims, Cleburne, Tex., Superintendent Water and Sewer System

Charles F. Tambling, M.A., Mt. Pleasant, Mich., with Department of Anatomy, Physiology and Physical Education, Central State Teachers College

Frank R. Theroux, M.C.E., Chicago, Ill., Sanitary Engineer

George H. Wandel, D.D.S., Riverside, Ill., Supervisor Bureau of Dental Health Education, American Dental Association

Marion Yang, M.D., Peiping, China, Instructor in Hygiene and Public Health, Peking Union Medical College, Chief, Division of Medical Service, First Special Health Area (Assoc.)

P. J. Alwin Zeller, College Station, Tex., Sewage Research, Texas Engineering Experiment Station

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Microbic Dissemination in Schools—After many years of experience the general consensus of opinion is that the isolation of infectious disease has in itself been of no material effect in reducing the morbidity as a whole, irrespective of any influence on age distribution or severity of infection.

The carrier and the individual with sub-clinical infection aggravate the situation. It has been found that in the London County Council Schools 2 per cent of the pupils are diphtheria carriers. It is estimated that the average carrier state remains for about 3 weeks. Therefore the number of carriers in the population as a whole changes 17 times during the year, and with a 2 per cent infection rate there would be 34 per cent of the population infected as carriers during the year. On the other hand, it was found that only 1 per cent of the population was infected with clinical diphtheria and therefore the carriers were over 30 times as numerous as cases in the London County Council Schools.

At the present time little impression can be made on the incidence of the minor droplet infections by attempts to isolate the distributors of them or increase the immunity of their receivers by means of a vaccine. A certain minimum number of bacteria are necessary in order to break down the natural immune defenses of man or animal. The time necessary to contract infection is the minimal infective dose divided by the difference between the rates at which infective material is received and destroyed. This differential rate may be called the velocity of infection.

At the Greenwich Hospital School there were no cases of diphtheria and scarlet fever among the day boys, while 300 infections occurred among the residents. This may be attributed to the more intimate and more extended personal contact in the dormitories.

Atmospheres which support droplets containing specific pathogenic bacteria act as vaccines and increase the resistance to disease of those who breathe them. The occasional immunity to measles among those giving no history of the disease may be explained on the theory that group or herd immunity to the minor respiratory diseases is increased through previous bacterial experience.

Among the pupils of the average London day school during the first 10 years of life, 40 per cent of the susceptibles will acquire immunity by autovaccination while 10 per cent will have succumbed to clinical diphtheria. In the residential or boarding school, such as the Greenwich Hospital School, double the number will have become immune within 3 years by autovaccination, but at a cost of 1 clinical case for every 3 immunized. This means of securing immunity may be compared to active immunization which within 6 months will protect approximately 90 per cent of the susceptible group.

As a means of curtailing the spread of communicable diseases by droplet infection more space should be given to individuals who sleep in dormitories and there should be an increased allotment of linear area available in schoolrooms. The small boy, being more susceptible and having received to a less degree the advantages of autovaccination, requires more space than the large boy. Efficient ventilation decreases the possibil-

ity of infection since a good flush of fresh air acts in two ways: first, it sweeps out the infected droplets, and, second, it prevents the humidity of the air from being raised by the water continually added to it from the lungs and skins of the occupants of the room. Mechanical ventilation has done much to prevent the spread of respiratory infection in the crowded sleeping quarters which, by force of circumstances, must be used on board ship. The danger to the group or herd exists, however, when one interferes with the process of nature which has resulted in the gradual autovaccination of large numbers with the resulting group immunity.—Sheldon F. Dudley, Microbic Dissemination in Schools, *Lancet*, 17: 849 (Oct. 27), 1928.

Diphtheria Prevention in Detroit—Prior to November 1, 1928, there occurred 1485 cases of diphtheria and 179 deaths in Detroit. Of these 179 deaths, 161, or 90 per cent, occurred among children under 10 years of age. Although the number of cases is not unusual, the number of deaths is particularly high. Furthermore all of these deaths are preventable and therefore the Health Department has renewed its campaign to secure the immunization of small children against diphtheria with toxin-antitoxin. Only toxin-antitoxin in goat serum is being used this year. This is to avoid sensitization to horse serum.

Prior to the current year 61,000 Detroit children between the ages of 6 months and 5 years had been protected against diphtheria. This represents 49 per cent of this age group. There remain 64,000 to be immunized. In addition to this 65 per cent of the primary school population has previously been immunized.

In previous years the Health Department has maintained infant welfare, school and special clinics at which immunization could be secured without charge. Various means have been used to advertise the clinics, including paid newspaper advertisements, press stories, posters, bill-board advertising, moving pictures, lectures, etc. The Metropolitan Life Insurance Company agents have been especially helpful in making home contacts, and reference slips were issued admitting children to the free clinics.

This year all free clinics have been abandoned. The usual advertising propaganda is being employed but all of the toxin-antitoxin will be given by private physicians. It is estimated that approximately 1,500 physicians are actively engaged in medical practice and each office becomes an immunization clinic. Any who can afford to pay will be expected to do so. The County Medical Society is suggesting a uniform charge of $1.00 for each immunization. The toxin-antitoxin is furnished by the Health Department. If the individual is without means, the physician, by arrangement, does the work and the Health Department pays $1.50 for each 3 doses of toxin-antitoxin.

This program has been worked out jointly by the Wayne County Medical Society and the Department of Health. There has been some adverse comment in one of the local papers but this publicity has had the good effect of impressing the public with the need for immunization.

Toxin-antitoxin is available at 8 established stations. A record is kept at each station of the amount of material taken by the physician and these reports are collected by the Health Department each evening. With the toxin-antitoxin the physician takes a postcard on which he reports each c.c. used, giving the name, address and age of the child and indicating whether it is the first, second or third dose. A similar card is used for the Schick test. Each physician hangs a poster furnished

by the Health Department in his waiting room recommending toxin-antitoxin for young children.

During the first 8 days of the campaign 1,200 postcards have been received by the Health Department indicating that over 1,000 children have commenced their series of toxin-antitoxin. It is anticipated that with the present plan more preschool children will be reached as the physician's office, which becomes a clinic, is more accessible to the population as a whole. Furthermore, there will be developed a certain consciousness among the physicians of the need of practicing preventive as well as curative medicine. The results may not be so immediately startling as those obtained under the free clinic plan, but ultimately the new procedure should be productive of more widespread interest in preventive medicine.—*Weekly Health Reviews,* Detroit Dept. of Health.

Health Work in Flood Area—Following the emergency establishment of sanitary control of the flood area in the Mississippi Valley in the spring of 1927, plans were developed for the formation of full-time local health service in more than 100 counties. Funds were raised by appropriations from the flood states, the counties, the U. S. Public Health Service and the Rockefeller Foundation. A training school was established at Indianola, Miss., where 235 health workers had received instruction prior to May 1, 1928.

An analysis has been made of the trend of disease incidence in the flood area before and after the flood occurred. Smallpox morbidity has shown marked reduction in 41 counties of the flooded area of Kentucky and Louisiana. In 55 counties in the same states the death rate for malaria has been decreased over a period of 10 years. Pellagra, which has been on the decrease in Kentucky for over 8 years, showed an increase in 1926 and 1927 while in Louisiana the death rate from pellagra has been constant for the 10-year period. The death rates for typhoid, infantile diarrhea and diphtheria for 1927 in the 55 flooded counties of Kentucky and Louisiana did not show any marked variation from the trend for the past 10 years.—C. N. Leach, Progress of Health Work in the Mississippi Flood Area, *J. A. M. A.*, 91: 1595 (Nov. 24), 1928.

Poliomyelitis After-care—The last legislative assembly in California passed an act requiring the State Health Department to provide such services as transportation, materials or appliances as are needed for the treatment of indigent children who have suffered from infantile paralysis. The cost including hospitalization and clinic service is chargeable to the county in which a child resides, the expense of administration being the only financial obligation of the State Health Department. In the year 1927 there were 1274 cases of poliomyelitis in California, of which 812 showed paralysis in one or more muscle groups; 205 were abortive; and 257 were of a type that has not as yet been determined.

The average cost per patient hospitalized under the terms of the recent act amounts to $1,000. The cost has been kept within this amount by a special hospital rate of $4.00 a day and a special operating fee made to the department of health by the orthopedic surgeons. The existing law has not been entirely satisfactory in view of the fact that the financial burden is too severe for some of the counties. It is suggested that some plan be evolved whereby the county pays one-third, the state one-third and some local welfare organization the other third.—W. M. Dickie, The After-care of Poliomyelitis, *J. A. M. A.*, 91: 1417 (Nov. 10), 1928.

LABORATORY

C. C. YOUNG

THE NEWMAN COMBINED FAT EXTRACTION, FIXING AND STAINING SOLUTION FOR USE IN THE DIRECT MICROSCOPIC TECHNIC FOR COUNTING BACTERIA IN MILK

ROBERT S. BREED, Ph. D., FELLOW A. P. H. A.

New York Agricultural Experiment Station, Geneva, N. Y.

IN the January, 1927, number of the *Monthly Bulletin* of the California State Department of Agriculture,* R. W. Newman, bacteriologist for the Dairy Laboratory of the Division of Chemistry of the California department, has been given three formulas that simplify the staining procedure for the direct microscopic technic for counting bacteria in milk. The author does not indicate which solution he prefers, so that many inquiries are being made in regard to the use of these solutions.

After several laboratories, including our own, had tried them out and found that the solutions were satisfactory for the purpose recommended, a footnote referring to them was inserted (p. 23) in the reprinted Fifth Edition of the *Standard Methods of Milk Analysis* † of the American Public Health Association. However, the formulas for the solutions were not given, so this has led to many further inquiries. After several months of experience in our own laboratory where we had found Formula No. 2 to be the most satisfactory, the author of this note wrote to Mr. Newman for a statement in regard to his experience and learns that he too regards No. 2 solution as superior to the others.

His letter reads:

> Of the three solutions, we are using and prefer Formula No. 2. We prefer this solution for two reasons: (1) because of the saving in time in the field as contrasted with Formula No. 1, and (2) because of the added "life" of the solution. Because methylene blue is so soluble in tetrachlorethane, the dye remains in solution even though the alcohol does evaporate. In Formula No. 1, on the contrary, the dye is not soluble in the xylene, and consequently is precipitated out of the solution as the alcohol evaporates. We found that the effective "life" of Solution No. 1 under field conditions was about 5 to 6 months. Solution No. 2 seems to give more satisfactory results in this respect as it does not seem to deteriorate with age. Solution No. 2 has been used exclusively by the inspectors of this department in grading milk in this state for the past two years.

Two persons have reported difficulty with Formula No. 3, apparently caused by impurities in the pyridine which dissolve the dried milk solids. Mr. Newman reports that a shipping clerk in the Eastman Kodak Company once misread a label and sent him tetrachlorethylene in place of tetrachlorethane. Mr. Newman also reports that in order to secure deeper staining he now adds 1.12 gm. of methylene blue per 100 c.c. in place of the 1.00 gm. originally recommended in Formula No. 2. This, however, appears to be a matter of personal pref-

* Also in *Proc. Soc. Exper. Biol. & Med.*, 24: 323–325, 1927.

† Obtainable from the Association, 370 Seventh Avenue, New York, N. Y. Price $.50.

erence as we have had no difficulty in using stains made up with the original formula. The formula recommended is as follows:

FORMULA NO. 2

Methylene blue powder, certified..	1–1.12 gm.
Ethyl alcohol, 95 per cent.....	54 c.c.
Tetrachlorethane, technical*.....	40 c.c.
Acetic acid, glacial.....	6 c.c.

Add alcohol to the tetrachlorethane in a flask and heat to a temperature not to exceed 70° C. (if it is desired to use methyl alcohol, the temperature should not be raised to more than 55–60° C.). Add the combined solution to the powdered methylene blue. Shake vigorously until the dye is completely dissolved. The original directions state that the glacial acetic acid should be added at this point, but Mr. Newman writes that it is better to *cool* the solution before adding acid and that the acid should be added *very slowly*. Further heating of the acid solution should be avoided. Filter and keep in a tightly stoppered bottle.

DIRECTIONS FOR USE

1. Prepare the milk smear.
2. When dry, immerse the smear in the solution and withdraw immediately.
3. Drain until dry (30 seconds).
4. Wash in water.
5. Dry and observe.

This solution permits much more rapid staining than does No. 1 and yields a clear, well stained preparation. The smears readily wash off the slide unless they are dried before washing (Step No. 3). If dried too rapidly the smears present a spongy appearance. If the smears are dipped in 70 per cent alcohol, this trouble may be prevented.

At this time it might be well to mention a simplification of the method of taking samples and preparing the slides that is entirely permissible where the counts obtained are to be used in educational work only, or where preliminary results are used as a means of finding milk supplies that need more careful examination later. In these cases, samples may be dipped from the weigh-vat with a dipper that is thoroughly rinsed in the milk that is to be sampled. The 0.01 c.c. pipette is then inserted directly into this dipper and this amount of milk withdrawn. The smear is spread immediately on a slide and placed on a suitable warm and level drying plate. Satisfactory drying plates are readily made by placing an electric bulb in a tin box. In the majority of milk plants, connections can be made to some electric light fixture with a suitable extension cord.

An experienced worker can prepare slides in this way with samples from each patron almost as rapidly as the milk is dumped and weighed. Ordinarily it is possible to stain the slides in spare moments so that the slides are ready for examination by the time all of the milk has been brought to the plant (usually 9 to 10 A.M.). Thus, it is quite possible to examine an average of 200 samples of milk per day with a great saving in the preparation of sample bottles, provision for icing samples and transportation to a suitable place for making the slides. A single worker using this simplified technic has collected and examined as many as 350 samples in one day.

* Obtainable from Eastman Kodak Co. Technical tetrachlorethane is relatively inexpensive.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Nineteen Twenty-eight a Good Health Year—General health conditions in the United States and Canada have been more than satisfactory during the first 9 months of 1928. In only two prior years, 1927 and 1921, has this year's health record, for any January–September period, been excelled. This is clearly indicated by the mortality record of more than 18,500,000 persons—the industrial policy holders of the Metropolitan Life Insurance Company, who comprise more than one-seventh of the combined population of the two countries. The death rate among approximately 16,000,000 white insured persons, this year, was 8.3 per 1,000. This closely approaches the minimum figures of 8.2, as recorded for the first 9 months of both 1927 and 1921. The rate for approximately 2,500,000 colored persons was 15.5 per 1,000, one of the most favorable mortality figures ever recorded for this large group of insured colored people.

The most important item in this year's health record is the continued drop in the tuberculosis death rate among the white industrial population. It is now entirely safe to announce that the end of 1928 will see the lowest mortality figure ever recorded for tuberculosis in the United States and Canada. Another extremely gratifying development this year is the indication that 1928 will very probably register the lowest death rate for puerperal diseases ever recorded among women in the industrial population. Here both white and colored insured women have shared in the gains. Still another disease, typhoid fever, seems destined to show, in 1928, a lower mortality figure than ever before. With the exception of measles, the four principal communicable diseases of children are causing fewer deaths than in 1927; and even with measles the death rate is well below the average. The improvement in the diphtheria situation is particularly gratifying. Last year the mortality from this disease rose somewhat, after showing a continuous decline over a series of years. Developments in 1928 indicate, however, that the 1927 rise was only a temporarily unfavorable phase of a generally improving situation. Influenza and pneumonia have caused more deaths than last year, but not more than the average. Alcoholism caused 434 deaths during this 9 months' period as compared with 427 during the corresponding months of 1927. The 9 months' mortality record for the external causes of death shows improvement over that made during the similar months of 1927. Deaths due to automobile accidents are still increasing among the colored, but, for the first time in the records of the company, the automobile fatality rate among white persons is lower than in the preceding corresponding period.—*Stat. Bull.*, Met. Life Ins. Co., 10: 1–5 (Oct.), 1928.

The Malaria Record of 1927—The incidence of malaria is very much localized in particular areas, chiefly those that still suffer from defective drainage. The malaria death rate in the registration area for 1926 was 1.9 per 100,000 population, and for 1925, 2.1 per 100,000. The data from 26 cities, chiefly in the South, show that the death rate has declined from 3.9 per 100,000 in 1923 to 2.0 in 1927. In 1923 the

LIBRARY, JAN 10

highest death rates in this group were 22.0 for Shreveport, La., and 15.1 for Tampa, Fla. In 1924 Shreveport again ranked highest with a death rate of 14.2 per 100,000. Augusta, Ga., had a rate of 11.0, and Memphis, Tenn., a death rate of 9.9. In 1925 the highest rate was reported for Augusta, Ga., with 10.9 per 100,000. In 1926 the highest rate was 11.8 for Shreveport, La., followed by Memphis, Tenn., with a rate of 11.3, and Augusta, Ga., with a death rate of 10.8 per 100,000. The highest death rates in 1927 were 10.7 for Augusta, Ga., and 10.5 for Montgomery, Ala. Jackson, Miss., not in the group of 26 cities, reported a malaria death rate of 20.8, which is one of the highest on record for recent years.

In Europe special efforts for malaria eradication are being made by the Health Section of the League of Nations. In Lithuania the number of malaria cases declined from 268 in 1922 to 51 in 1926. In the region of Galatz, Roumania, the number of cases was reduced from 49,896 in 1924 to 20,176 in 1926 as the result of sanitary measures. In the territory of Soviet Russia there was a reduction of about 860,000 cases between 1924 and 1925, and a reduction of 670,000 cases between 1925 and 1926.—Frederick L. Hoffman, *Spectator*, 121: 35–36, 38 (Nov. 15), 1928.

Scottish Vital Statistics, 1927—The seventy-third annual report of the Registrar-General for Scotland records the estimated population of Scotland in the middle of 1927 as being 4,891,953. The deaths registered during the year numbered 65,830, and the death rate was 13.5 per 1,000 population. The deaths for the year were 2,050 more than in 1926. The births for 1927 numbered 96,672 with a birth rate of 19.8 per 1,000. The birth rate for the year is 1.2 less than that of the previous year, and 2.3 less than the mean of the preceding five years. It is the lowest Scottish birth rate yet recorded, the previous lowest being 20.3 in 1917. Subsequent to the termination of the World War, the Scottish birth rate rose and attained a maximum of 28.1 per 1,000 in 1920, but it has since then steadily decreased.

In 1927 the death rate from malignant disease was 141 per 100,000 population. In 1926 it was 136 and averaged 132 for the preceding 5 years. The total death rate for tuberculosis was 100 per 100,000 population, while from tuberculosis of the respiratory system it was 71 per 100,000. There was a death rate of 6.4 per 1,000 registered births for diseases and accidents of pregnancy and parturition. There were 152 deaths by coal gas poisoning for the year and 448 from motor car accidents.

A relatively small proportion of children born in 1926 were reported to have been successfully vaccinated. Of the 36,376 unvaccinated children, 30,804 were exempted from vaccination because of conscientious objection on the part of their parents.—*Med. Off.*, 40: 158 (Oct. 13), 1928.

Public Health in Western Samoa—The population of Western Samoa was 42,865 on December 31, 1927. It consisted of 39,215 Samoans, 2,564 Europeans, 939 Chinese laborers and 147 Melanesian laborers. The births of 1,636 living children were registered during 1927, giving a birth rate of 42.4 per 1,000 of the native population. The deaths numbered 495, giving a death rate of 12.8. The increase of the population was 29.6 per 1,000, and this is far in excess of the natural increase of any European country. In 1926 there was a birth rate of 52.6 and in 1925, 56.3. The death rates for 1926 and 1925 were 19.4 and 23.8 respectively. The decrease in mortality is probably due to a reduction of epidemic disease. In 1925 there was an

epidemic of whooping cough which caused over 200 deaths. In 1926, 53 deaths were due to an outbreak of dysentery and 25 were attributed to an influenza epidemic. In 1927 there was no epidemic disease. The infant mortality rate was 101 per 1,000 live births in 1927, 106 in 1926, 186 in 1925 and 153 in 1924.

There were 46 cases of lobar and 8 of bronchial pneumonia treated in the hospital. There were 9 pulmonary, 2 peritoneal and 6 meningeal tuberculosis cases treated. Three cases of puerperal septicemia and 23 cases of enteric fever were treated. More and more cases of cancer among Samoans are coming to light. Fourteen cases, of which 7 were carcinoma of the stomach, 3 of the intestines and 2 of the uterus, were treated during the year. An extensive campaign against hookworm and yaws commenced in 1923. Treatment was given for 606 cases of hookworm during 1927, and no bad cases were found. The total number of N. A. B. injections against yaws was 7,450.—Public Health in the Mandated Territory of Western Samoa, *League of Nations Epidemiological Report,* Oct. 15, 1928, pp. 379–380.

Medical Conditions in the South Pacific—The infant mortality in the islands of the South Pacific is very high, being estimated previous to 1922 at 200 to 300 per 1,000 births. In 1923 there was an infant mortality rate of 167 per 1,000 births in Fiji, a rate of 136 in Tonga and 200 in Western Samoa. General health measures had reduced the rates by 1926 to 155 for Fiji, 102 for Tonga and 106 for Western Samoa, although an epidemic of whooping cough in 1925 caused the abnormally high infant mortality rates of 172, 295 and 186 per 1,000 births in the three respective districts. Modern principles of medicine maintained the birth rate in Western Samoa at over 50 and reduced the death rate to under 20 between 1923 and 1927.

Yaws is common among the people of the Pacific Islands, and was a great problem until the recent introduction of arsenicals for treatment. Syphilis is rare seemingly because of the prevalence of yaws. Leprosy is common and spreading in the New Hebrides, but is not so prevalent in the Solomon Islands and New Guinea. Vaccination against smallpox is given in the ports of Papua and New Guinea. Fiji vaccinates a few thousand each year, but otherwise native populations are protected only by quarantine at ports of entry. Measles is now endemic in Fiji, Samoa, Tonga, the Cook Islands and the New Hebrides, and diphtheria occurs in a mild form in many of the islands. Tuberculosis is the immediate cause of more deaths than any other disease in the Pacific. The commonest form in which it appears is pulmonary tuberculosis. Glandular and peritoneal tuberculosis are less common and bone infections are rare. There have been epidemics of influenza in the islands for over one hundred years. In 1918 from 10 per cent to 20 per cent of the various native groups died from influenza. Typhoid fever occurs in a mild form in Melanesia but in Fiji, Tonga and the Cook Islands it is at times endemic or epidemic. The control of malaria is one of the most difficult problems in the islands, and in such countries as Papua, New Guinea, the Solomon Islands and the New Hebrides would be an impossible expense. The whole southern coast of Papua is malarious although this condition diminishes in the Delta Region of Western Papua. Samoa and Tonga are the most forward of the groups in sanitation and water supply, but in most of the villages very primitive conditions exist.—S. M. Lambert, *M. J. Australia,* 2: 362–378 (Sept. 22), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

DISCUSSION OF "SANITATION OF WATERSHEDS"*

Warren J. Scott, Director, Bureau of Sanitary Engineering, Connecticut State Dept. of Health, Hartford, Conn.—Possibly it is because I too am from New England that I agree with Mr. Chase's discussion in that it advises that caution should be exercised in the modification of the old New England policy of reliance upon clean watersheds and storage for water supplies relatively free from pollution.

It seems to me that the committee † of this Association referred to by Mr. Chase has gone rather far in its emphasis on the remoteness of the dangers of bathing in public water supplies and of other recreational uses. It is difficult for a committee to generalize on policies which must of necessity vary for different sections of the country. I do not blame the committee for recognizing that the limitation of the recreational use of watersheds must be on a reasonable basis.

It is true that public opinion, in the face of too strict standards, may force a complete about-face and let down the bars too far. In some cases, the derivation of a small water supply from a large watershed under too strict regulation may work a hardship on a far greater number of persons than are benefited. The reverse is usually true in Connecticut. Another consideration is the taking of watersheds that are now used for purposes of recreation for additional water supply purposes.

On the other hand, advocacy of the relaxation of present standards for clean watersheds as practiced in New England and elsewhere should certainly not emanate from public health authorities or public health associations.

In most of New England, the statute law with regard to bathing, fishing, and other recreational uses, appears to be based upon the fact that to drink the water or to secure it uncontaminated is the primary right. Bathing and other recreational uses which pollute the water are considered as a secondary right which may be taken away as a matter of public policy.

Looking at the question of recreational use of water supplies solely from the standpoint of health, what happens if water supplies now dependent only upon clean watersheds and some storage are opened for unrestricted recreation? It may be said that the community using the water will have to install treatment. If treatment is adopted and properly supervised, the health hazard may be less than formerly. Treatment, of course, is always desirable as an additional form of protection. But would treatment be installed in many cases? and if so, what would the type of treatment be? In many of our small New England communities using small gravity supplies with widely varying rates of consumption, chlorination is difficult and unreliable unless it is possible to install an equalizing reservoir. The latter may be comparatively expensive for a small

* In the November, 1928, issue of the JOURNAL, there appeared a paper by E. Sherman Chase on Sanitation of Watersheds. Viewpoints of others on the same question, while not always in agreement, usually are enlightening. Hence, two discussions of Mr. Chase's paper are presented here.

† Committee on Water Supplies.

community, and this might also be true of filtration. Even if treatment were installed on a small water supply, it might be poorly supervised, with resultant danger. The answer then, from the standpoint of the health worker, is that the community is likely to face another distinct health hazard which does not now exist. And yet the benefits from the recreational standpoint may be slight.

It is possible that public opinion may eventually bring about a modification of our present New England policies, and if so, the problems attendant on such modification will have to be met. Possibly the use of a new water supply which takes away existing benefits of recreational use should be accompanied by suitable treatment to avoid the loss of these benefits. Additional treatment works and land purchases may be required to an increasing degree to overcome the dangers from less stringent watershed regulations. But as public health workers, it seems to me that we should work toward making any changes gradually. We should not belittle the very real dangers of recreational use of water supplies any more than we should close our eyes against the need for a reasonable public policy. Any modification of existing policies should be made with due regard to the local conditions and after due consideration of the hazards created and the practicability of adoption of means of combating them as well as the recreational benefits to be derived.

H. E. Moses, Asst. Chief Engineer, Pennsylvania State Dept. of Health, Harrisburg, Pa.—Properly the author confines the subject to the sparsely settled watershed, where control measures have a reasonable chance of being effective. Here two main problems must be dealt with; namely, those relating to:

1. The permanent population on the shed
2. The transient population on the shed

With respect to the first, state laws and regulations, where adequate, permit health departments to enforce sanitation measures. These will be effective in so far as they are practicable and as the laws are wisely administered. But the real problem—and the growing one—has to do with the transient population passing over the watershed. We may have uninhabited watersheds but the unvisited catchment area is fast becoming a rarity.

Possibly the most pressing need relates to the hazard created by the recreational use of watersheds. This includes camping, hunting, fishing and bathing. These practices raise real problems for the water works officials and the health authorities. Fishermen are insisting on their so-called inherent right to use not only the streams but also the reservoirs for fishing purposes. Camps and colonies on watersheds are rapidly increasing, and swimming and bathing are growing in popularity.

Akin to this phase of the question is the matter of riparian ownership of land abutting on water used as a source of public water supply. It is understood that such riparian owner has an inherent right to the reasonable use of the stream, including bathing, for himself, his family, servants, and invited guests. This probably holds so long as the riparian owner does not commercialize this use of the stream.

The solution of the problem must be reasonable and practicable and at the same time not serve to arouse such antagonism as to result in adverse legislation. A good example of the extremes to which a legislature may go when sufficiently urged by the people is the New Jersey case where in 1927 the Legislature passed an act which was vetoed by the governor, repassed over his veto, and is now a law. This statute reads: "It shall be lawful to bathe or swim in any of the fresh waters

of this state, provided that in so doing no trespass be committed. This act shall take effect immediately." This case probably represents an extreme measure but is cited to show a tendency in that direction.

In an attempt to find some measuring stick of more or less general application these two general principles are suggested:

First, where the reservoir does not have a nominal long-time storage and where ways and means have not been installed or are not being operated to safeguard the sanitary quality of the water delivered to the consumers and where the catchment area is relatively uninhabited and untraversed by much traveled highways, the recreational use of the catchment area does constitute a menace to the public health.

Second, where the nominal retention of the water in the reservoir can be construed as adequate long-time storage, and where ways and means have been installed and are being operated to safeguard the sanitary quality of the water delivered to the consumers, and the catchment area is inhabited or traversed by extensively used highways, the recreational use of such a catchment area does not constitute a menace to the public health because the persons so using these areas do not add an undue burden upon the self-purification to be obtained from the assured long-time storage and from the artificial ways and means which have been installed and are being operated to safeguard the sanitary quality of the water delivered to the consumers. Hence, in such cases, consideration might be given to permitting the public a restricted use of the watershed area, exclusive of the reservoir and the margins thereof.

Certain protective measures, some of which have been mentioned by Mr. Chase, merit brief discussion:

1. Ownership of Watershed—This is basically an economic problem and must be determined by the respective merits of ownership versus protective measures and purification. Its effectiveness is dependent on the extent of watershed control and grows less practical as the size of the watershed increases. Where it owns the watershed, the water company can invoke trespass laws. Certainly the reservoir site and the shore margins should be owned or definitely under the control of the water company.

2. Zoning—This practice is not applicable except on company controlled or state owned land. Elsewhere private ownership prevents.

3. Placarding—This is practical on small areas. Its effectiveness is uncertain but it is probably beneficial.

4. Sanitary Control—Within rather circumscribed limits, it can be administered under existing laws, health regulations and with available personnel.

5. Education of Public—Undoubtedly this is of value, but it must be persistent and continued. It will not control the careless or vicious.

6. Legislation—This must be reasonable, capable of enforcement, with sufficient elasticity to be applicable to the varying conditions encountered. If it is too drastic, it is difficult of enforcement and arouses militant opposition, possibly defeating its purpose, which may be entirely proper.

But after all, must not these be considered as palliatives, and, valuable as they may be, as not solving the problem completely.

We in Pennsylvania have come to believe that no surface supply, valuable as may be the sanitation measures on the watershed—and they are needed—is safe without at least chlorination. This is heresy, perhaps, but nevertheless our profound conviction.

Sewage Agitation and Chlorination Tests at Havre, Mont.—During the summer months the Milk River, on which Havre is located, has not suffi-

cient flow adequately to oxidize the city's sewage. An agitation and chlorination plant was established at the outlet of one of three main sewer outlets with the following results:

Agitation reduced suspended solids from 0.882 per cent to 0.102 per cent, a reduction of 88 per cent; no marked difference was noted in the amount of settleable solids before and after agitation. With agitation only, there was an average reduction of hydrogen sulphide of 26.5 per cent (from 4.08 to 3 p.p.m.); agitation combined with chlorination gave an average reduction of hydrogen sulphide of 63 per cent; bacterial reductions were great; chlorine residual after 10 minutes was maintained between 0.5 and 1.0 p.p.m.; cost of operating plant one month was estimated at $110. This plant treated about 0.122 m.g.d.—Emil Sandquist and H. B. Foote, *Eng. News-Rec.*, 26, 100: 1001–1002 (June), 1928. Abstr. R. J. Faust.

Treatment of Tomato Cannery Wastes—Experiments conducted by the Bureau of Sanitary Engineering of the Maryland State Health Department at a tomato canning factory indicated that the liquid wastes could be clarified by precipitation with 6 gm. of lime and 4 gm. of ferrous sulphate per gal., or by absolutely quiescent sedimentation for 18 to 24 hours without the use of precipitants.—Anon., *Pub. Works*, 2, 59: 65 (Feb.), 1928. Abstr. D. E. Kepner.

Experiences with Covered and Open Reservoirs—Three years' bacterial, microscopic and chemical tests on an open and a closed reservoir in the city of Washington, D. C., both receiving the same supply from the slow sand filtration plant, chlorination then being intermittent, showed the following:

Average bacteria count 4 for filtered water, 7.6 for the covered reservoir, an increase of only 90 per cent, compared with 44 for the open basin, an increase of 1,000 per cent. There was no growth of microörganisms in the covered reservoir, whereas it was abundant in the open. Albuminoid ammonia, nitrate and nitrate tests also all showed much better conditions in the covered basin at all times.—Carl J. Lauter, *Eng. News-Rec.*, 25, 100: 963–964 (June), 1928. Abstr. R. J. Faust.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Special Bibliographies Available—Those who are interested in the bibliographies prepared by the below mentioned committees, which bibliographies are too extensive to be included with the published reports of the respective committees, may obtain the same by addressing the chairmen of the committees in question, or the secretary of the Industrial Hygiene Section, Carey P. McCord, M.D. (Industrial Conservancy Laboratories, 34 W. 7th St., Cincinnati, Ohio). Bibliographies cover recent years:

Industrial Fatigue and Allied Subjects, Eugene L. Fisk, Chairman of Committee, c/o Life Extension Institute, 25 W. 43d St., New York, N. Y.

Lead Poisoning in the United States, Carey P. McCord, Chairman of Committee (see address above).

Skin Irritants, Henry Field Smyth, Chairman of Committee, Laboratory of Hygiene, University of Pennsylvania, Philadelphia, Pa.

The Compensation Law and Its Application to Lead Cases—The New York law schedules 19 occupational diseases subject to compensation, and defines disability as "the state of being disabled from earning full wages at which the employe was last employed." Occupational disease disablement is treated as an accident with the right to compensate within 12 months of contraction. Presumption as to the cause of an occupational disease is deemed acceptable if the exposure has been to one of the processes mentioned in the second column of the schedules of diseases. The term "lead poisoning" lacks a standard definition of general acceptance. Some will not diagnose a case of lead poisoning unless colic is present; still others only when the presence of stippled cells is noted, etc. Due to this confusion it has been put forward from the standpoint solely of medical terminology that this term be arbitrarily and definitely confined only to the toxic episodes, namely, colic, lead palsy, or encephalopathy; and that "lead absorption" be used to cover all other cases of lead which has been absorbed into the body. Considered from this point of view "lead poisoning" becomes a subdivision of lead absorption—the term "poisoning" being confined to cases of lead absorption presenting acute manifestations.

The plain intent of the New York law is to compensate the given disease well before the acute stage results in total disability, so that the term "lead absorption" is synonymous under the law with the term "lead poisoning." For this reason it is argued that the former term be substituted for the latter in the compensation law. The following fundamental points regarding lead absorption should be kept in mind:

1. In any given individual, lead may be present in his body either in toxic or non-toxic form. In an individual where all of the lead present in his body has been stored in his bones, it is non-toxic to him for the time being.

2. Lead which is present, however, in the circulating blood may be either toxic or non-toxic, depending upon the quantity of lead present. It is only in those cases where toxic quantities of lead appear in the circulation that any incapacity may occur, and it is only those cases which are, therefore, of any interest to the Compensation Tribunal.

3. Lead workers are just as subject as any individual to the ordinary ailments such as ordinary stomach ache, gastric ulcer, ap-

pendicitis, etc. It is quite obvious, therefore, that all other causes be definitely eliminated in considering the health of a lead worker quite as much as in making a differential diagnosis in any other individual.

Confining ourselves to those cases where lead is thought to be actively present in the body in toxic amounts, resulting in clinical manifestations of disability, we may divide these for the present purpose into two groups, depending upon whether the manifestations are such as to produce definite demonstrable disability, or are merely subjective, resulting in a claimed disability, the existence of which may be difficult to prove.

I. Cases with Positive Disability
   A. Cases with Positive Laboratory Findings (Procedure given)
   B. Cases with Negative Laboratory Findings (Procedure given)
II. Cases with Doubtful Disability (Diagnostic Possibilities)

The importance of laboratory examinations of both blood and urine in every lead case cannot be overemphasized.

A new bulletin on the subject of Lead Poisoning in New York State, with special reference to the study of the health of 381 lead workers, is now in the hands of the printer and will be ready for distribution in the near future. This bulletin will be mailed to anyone interested, upon request.—May R. Mayers, *Indust. Hyg. Bull.*, N. Y. State Dept. of Labor, V, 4 (Oct.), 1928.

A New Test for Industrial Lead Poisoning—Following upon a previous report by McCord, Minster, and Rehm in 1924, the author gives the summary and later experience with his counting method of estimating the number of basophilic cells in cases of lead poisoning. The importance of lead poisoning includes its ingestion without absorption, with absorption, and with intoxication. Immature red cells are produced in the bone marrow having certain characteristics of which basophilic substance appears to be the most constant and includes polychromatophilia or polychromasia, punctate stippling and basophilic aggregations. The methods of detecting basophilic material with Wright's stain, Robertson's method for counting of reticulated cells, also Cunningham's method, the Friedlander-Wiedemer method of enumeration of basophilic red cells and the basophilic aggregation test of the author are reviewed. Clinical and laboratory materials necessary are given, also illustrations of blood findings and a discussion of basophilic red cells in normal persons and as an index of exposure to lead, and in clinical lead poisoning with case citations.

Among fifteen points included in the summary are these: The number of basophilic red cells found in 145 normal adults was commonly less than 1,000 per cu. mm. of blood, and rarely exceeded 5,000 in certain physiologic states. The number of such cells is increased above normal in the following pathologic states:

Lead intoxication, benzol poisoning, arsenic poisoning, in all types of anemia in which there is regeneration, hemolytic icterus, following hemorrhage, leukemias, at times in acute infections, in neoplasms involving the bone marrow, and in polycythemia.

In the absence of other conditions presenting high basophilic red cell counts a high basophilic red cell count in a person exposed to lead is accepted as indicative of lead absorption or lead poisoning.

The application of these methods suggests that in lead industries many workers commonly regarded as unexposed, such as office workers, clerks, etc., actually may also absorb much lead and thus become potential cases of lead intoxication. This is especially true if the hazard of lead is in the form of dust.—Carey P. McCord, *U. S. Bur. of Labor Statistics*, No. 460 (Apr.), 1928, 33 pages.

Health of Workers in Dusty Trades—The U. S. Public Health Service has completed a study of the health of workers in a Portland cement plant, the first of a series covering the dusty trades, according to an announcement recently made by Surgeon-General H. S. Cumming. The study was undertaken to ascertain whether persons

working in an atmosphere containing numerous minute particles of a calcium dust suffered any harmful effects. The investigation was conducted in one of the older, dustier plants, so that the effect of large quantities of the dust could be observed. Records of all absences from work were kept for 3 years, and the nature of disabling sickness was ascertained. Physical examinations were made, X-ray films taken, and the character and amounts of dust in the atmosphere of the plant were determined.

The results of this investigation indicated that the calcium dusts generated in the process of manufacturing Portland cement do not predispose workers to tuberculosis nor to pneumonia. The workers exposed to dust experienced, however, an abnormal number of attacks of diseases of the upper respiratory tract, especially colds, acute bronchitis, diseases of the pharynx and tonsils, and also influenza, or grippe. Attacks of these diseases serious enough to cause absence for two consecutive working days or longer occurred among the men in the dustier departments at a rate which was about 60 per cent above that of the men in the comparatively non-dusty departments. Limestone dust appeared to be slightly more deleterious in this respect than cement dust.

Outdoor work in all kinds of weather such as was experienced by the quarry workers appeared to predispose to diseases of the upper respiratory tract even more than did exposure to the calcium dusts. In the outdoor departments of the plant, also, the highest attack rates of rheumatism were found. The study also indicated that work in a cement dusty atmosphere may predispose to certain skin diseases such as boils, to conjunctivitis, and to deafness when cement dust in combination with ear wax forms plugs in the external ear. When the dust in the atmosphere is less than about 10 million particles per cu. ft. of air it is doubtful whether the above-mentioned diseases and conditions would be found at greater than average frequency.

Modernization of plants and installation of ventilating systems are helping to solve the dust problem of the industry.—*Health News*, U. S. P. H. S., E-19, 1928.

Industrial Hygiene in Model Health Ordinances—The following is excerpted from the Progress Report of the Sub-Committee on Model Health Ordinances, presented at the Chicago meeting of the American Public Health Association, October 15, 1928:

Institutional and Occupational Care

1. There should be an ordinance giving the Board of Health authority to license and supervise certain classes of occupations and institutions relating in any way to public health and such regulations should include hospitals, dispensaries, institutions, laboratories, homes for children, midwives, and occupations likely to be a hazard to health.

Industrial Hygiene

1. There should be an ordinance which provides that all manufacturing and industrial plants where processes are used which are dangerous to the health of the workers be subject to special rules and regulations of the Board of Health.

Health Hazards in Chromium Plating—Chromium plating is developing rapidly in the United States. It has long been known that, in the manufacture of chromic acid and chromates, the operators are subject to attack by an ulcerative process and perforation of the nasal septum; and to the formation of ulcers or "chrome holes" upon the hands or other exposed parts of the body. Accordingly, some provisions have been made in all chromium plating plants for artificial ventilation and for other sanitary measures. In spite of these precautions, however, the employes in some plants have been affected in the above mentioned ways.

In order, therefore, to determine the extent of the hazard and the best means of overcoming it, a survey was conducted in several commercial plants. This included a study of the methods and degree of ventilation, of the concentrations of chromic acid in the air breathed by the workers, and a physical examination of the workers themselves. Although only 6 plants were visited, and 23 persons examined, the results were so consistent in different plants, and agreed so well with previous experience with chromates, that certain tentative conclusions and recommendations are warranted.

It was found that exposure to very low concentrations of chromic acid, e.g., one mg. in 10 cu. m. of air, or 1/60 gr. in 350 cu. ft. (which may be considered approximately the volume of air breathed by a worker in eight hours), is sufficient to cause nose bleed and nasal inflammation in a week or less. Higher concentrations or longer exposures cause extensive attack and even complete perforation of the nasal septum. This is painless, however, and the operator may be entirely unaware of the perforation. Many of the employes were found to have chromium ulcers on the hands or other exposed parts of the body. No evidence was found of injury to the respiratory tract except in the nose, nor of any effect upon the digestive system or the kidneys.

While, therefore, there is a real hazard in chromium plating, it is not critical, and can be entirely eliminated by suitable measures. These should include an effective system of ventilation in which the air is drawn horizontally across the plating tanks into a narrow duct in which the air velocity should be about 2,000 feet per minute. So far as possible, rubber gloves, aprons, and shoes should be worn. Frequent applications of vaseline or mentholatum salve to the nose and hands greatly reduce the danger of ulceration. All cuts and abrasions of the skin should receive regular inspection and medical treatment.

If these simple, entirely practicable measures are taken, the hazard can be practically eliminated. There is no reason, therefore, to fear any serious injuries from the extension of chromium plating that is likely to occur in the next few years.—*Health News*, U. S. P. H. S., 38, 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Continued Administration of Iodide and Other Salts. Comparative Effects on Weight and Growth of the Body—Criticism directed against the continued administration of iodide in small amounts and the lack of any study of the action of these compounds over long periods has prompted this investigation. Experiments were carried on for a period of 4 years with rats as experimental animals. The rats were maintained on an adequate diet which included yeast, cod liver oil, and Osborne and Mendel salt mixture which contains about 0.0032 per cent of potassium iodide. Dry sodium iodide was administered in a concentration of 0.01 per cent, corresponding to approximately 1 mg. daily per rat, a dosage corresponding to about 0.23 gm. (3½ gr.) daily for an adult of 70 kg. body weight. This dosage corresponds to the iodide

medication in simple goiter and for certain chronic inflammations and is much greater than the daily dose of iodide received from the use of iodized table salt.

Other salts were tried: sodium sulphocyanate in concentration of 0.007 per cent; sodium bromide, 0.0054 per cent, representing respectively daily doses of about 0.6 and 0.5 mg.; arsenic, as Fowler's solution, in concentration of 0.01 per cent of arsenous oxide, the daily dose per rat being 0.76 mg. arsenic trioxide; sodium borate in a concentration of 0.014 per cent, the daily dosage being 1.12 mg. per rat; thallium acetate in a concentration of 0.0014 per cent, or 0.11 mg. per day per rat. Results are shown in graphs, curves representing median values at the end of each month, although weekly records were kept. The conclusions with respect to iodide are: (1) increase in body weight or growth some time during the course of the experiment; (2) in contrast with the iodide and generally with the controls, reduction in body weight and growth after medication with other salts. Approximately for all iodide groups the increase is about 10 or 15 per cent. Rats on the iodized food consumed the same amount as controls on untreated foods, and the body weight increases are apparently, therefore, independent of the food consumption. Only one group showed a loss of body weight over a period of 7 months but the consumption in this case was 6 per cent less than that of the controls. Rats on a deficient diet were given iodide, also arsenic and manganese. The iodides improved growth and prolonged life while rats on arsenic and manganese showed loss in weight and earlier death than both the iodide and the control rats. The results with other salts showed that sulphocyanate was responsible for a loss in body weight of approximately 10 per cent and the daily consumption of food was also less. With arsenic in two experiments losses in body weight of 20 and 10 per cent respectively occurred and food consumption was reduced about 22 and 10 per cent. Sodium borate, over 7 months, caused an approximate loss of 17 per cent in body weight and a reduction of food consumption of 10 per cent. Thallium acetate was the most toxic of all, causing the death of one group at the end of 4 months. Body weight was decreased 13 per cent and food consumption 16 per cent. The depilatory action of thallium appeared at the end of 6 weeks and sudden fatalities in the rats appeared disproportionately with the loss of weight and food consumption. Sodium bromide resulted in a loss of 11 per cent body weight and 2.2 per cent in food consumption. These experiments confirm the work of previous investigators in reference to the toxic effect of arsenic and boron and correlate the recently reported experiments on the increase in production of milk after the administration of iodides to cows. The authors conclude that there is no ground for the belief that continued use of small doses of iodides under ordinary conditions would have a deleterious effect but there is reason to believe that it will be beneficial. The conclusions, however, do not apply to the administration of the drug in large doses.—P. J. Hanzlik, E. P. Talbot, and E. E. Gibson, *Arch. Int. Med.*, 42: 579 (Oct.), 1928.

Dietary Requirements for Fertility and Lactation: The Vitamin A Content of Wheat Oil—This study was undertaken to determine the vitamin A content of wheat oil in view of conflicting reports of other investigators, particularly since wheat oil is used by most investigators for the study of vitamin E. Young rats, after weaning, were allowed to remain with the lactating mothers on a diet deficient in fat-soluble vitamins until the development of ophthalmia. Wheat oil was adminis-

tered separately from the ration in carefully measured graduated amounts and the controls received comparable amounts of cod liver oil. The wheat oil was administered in dosages of 0.01 c.c., 0.05 c.c. and 0.1 c.c. per animal per day. The animals were weighed twice a week and food consumption records kept. In the experiment in which 0.01 c.c. wheat oil was fed not all the animals maintained good growth, and the results show that this amount is not even comparable with 0.01 c.c. cod liver oil for vitamin A. Better results were secured with the administration of 0.05 c.c. wheat oil. A daily dosage of 0.1 c.c. wheat oil resulted in completely clearing advanced ophthalmia in 17 days. It is noted that the rats on wheat oil which was ineffectual in curing ophthalmia showed a marked reduction in food intake until complete inanition occurred. It is concluded from this that the vitamin A is an important factor, together with vitamin B, in conditions of anorexia. This experiment shows conclusively that there are appreciable amounts of vitamin A in wheat oil sufficient to maintain excellent growth for a period of 10 to 16 weeks.—Barnett Sure, *J. Agri. Res.*, 37: 93 (July 15), 1928.

Blood Regeneration in Severe Anemia. XII. Potent Influence of Inorganic Ash of Apricots, Liver, Kidney, and Pineapple—Two of the authors (Robscheit-Robbins and Whipple) observed 8 years ago that apricot feeding had a beneficial effect in experimental anemia in dogs. Two hundred gm. of this fruit (or peaches) increased the hemoglobin 40 to 45 gm. above the controls for a 2-week period. Since the salts were regarded as a potent agent, this experiment was undertaken to observe the effects of feeding ash to anemic dogs. Standard bread was used which maintains the hemoglobin production at a low level, 1 to 3 gm. of hemoglobin per week. A method is given for the preparation of pure ash from liver and other substances without adding any chemicals to aid incineration. The ashes were analyzed for organic matter, silica, copper, antimony, iron and aluminum, calcium, magnesium and phosphates. Apricot ash proved a stimulant to hemoglobin production over a 2-week period from 42 to 65 gm., the average of the whole series being 40 to 50 gm. hemoglobin. Liver ash feeding over the same period shows production of 38 to 65 gm. hemoglobin above controls. The liver ash experiments showed the same "carry over" into 2 or 3 weeks of the after period as noted with fresh liver. Kidney ash is similar to liver ash. Pineapple ash was found much less potent than other ashes. This product was not prepared by the experimenters but was obtained from Hawaii. A table is given of the average values of the elements in the ash analyses in which it is noted that copper is high in the apricot ash but abundant in all. Iron is also abundant but more so in kidney ash. Experiments show that the ash of dried apricot retained most of the potency of the whole apricot but that beef liver and pig kidney each contains about one-half the potent factors present in the whole cooked organs.—Frieda S. Robscheit-Robbins, C. A. Elden, Warren M. Sperry, and G. H. Whipple, *J. Biol. Chem.*, 79: 563 (Oct.), 1928.

Blood Regeneration in Severe Anemia. XIII. Influence of Certain Copper Salts upon Hemoglobin Output—The presence of iron and copper in ash of certain foods which have been shown to have a profound effect in blood regeneration in severe anemia has led to a study of the inorganic constituents, particularly iron and copper salts. Copper sulfate in small doses, 65 mg. copper (252 mg. of copper sulfate per day), results in increase of about 20

gm. hemoglobin over a 2-week period. Larger doses of copper cause lack of appetite. Copper tartrate was found to be no more potent than copper sulfate. Copper salts mixed with iron salts are much more potent than copper salts alone. Twenty mg. of copper and 36 mg. of iron as metal in daily doses resulted in an increase of 42 to 80 gm. hemoglobin over a 2-week period. An experiment in which a large dose of ferric chloride and an average dose of copper tartrate were given showed an increase in hemoglobin which was regarded as no more than that which would be due to the iron alone. Similar experiments with copper and zinc resulted in hemoglobin production no more than would be expected from the amount of copper alone.—C. A. Elden, Warren M. Sperry, Frieda A. Robscheit-Robbins, and G. H. Whipple, *J. Biol. Chem.*, 79: 577 (Oct.), 1928.

The Iodine Content of Cape Cod Cranberries—The iodine content of cranberries grown in southeastern Massachusetts is of interest because of the nearness of the sea, which affects the ground waters. Three lots of cranberries were analyzed—one from stored crates awaiting shipment, one from a bog on a strip of land called Sandy Neck, and the third from a bog in the center of Nantucket Island. Several charges of 500 gm. each were analyzed by the method of Von Fellenberg. Cranberries from Sandy Neck, which is nearest to the sea, showed 35 parts iodine per billion, while those from the crates showed 26 parts per billion and those from Nantucket showed 27 parts per billion. Von Fellenberg (*Biochem. Ztschr.*, 139: 371, 1923) reported figures showing iodine content of certain foods as follows: apples without cores 1 to 6 parts of iodine per billion; orange pulp 16 parts; potatoes 11 to 18 parts; cabbage 6 to 20 parts; lettuce 6 to 18 parts. When compared with these figures, cranberries from southeastern Massachusetts have a relatively high content of iodine.—Fred W. Morse, *J. Biol. Chem.*, 79: 409 (Oct.), 1928.

A Comparison of Raw, Pasteurized, Evaporated and Dried Milk as Sources of Calcium and Phosphorus for the Human Subject—Calcium and phosphorus balance experiments were carried out in 3 series, both children and adults being used as subjects. Foods were bought in quantity so that the composition would not vary. A standard brand of dried milk made by the spray process and a popular brand of evaporated milk were used in all experiments. Tables are given showing the different foods and amounts given, together with the calcium and phosphorus balances. Experiments with five children showed that the child retains more calcium when it is supplied in fresh milk than when supplied in dried milk. All adult subjects showed more favorable calcium balances with fresh milk than with dried milk. Pasteurized milk was less favorable than fresh milk while milk from cows which were kept in a barn away from sunlight was less favorable than the fresh milk. Evaporated milk showed balances as good as fresh milk. Phosphorus balances were about the same as the calcium although the amount of milk used supplied smaller proportions of the phosphorus of the diet.—Martha M. Kramer, Esther Latzke, and Mary Margaret Shaw, *J. Biol. Chem.*, 79: 283 (Sept.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

Preschool Health Supervision in a Large City by a Voluntary Agency—The Minneapolis Infant Welfare Society as a result of 8 years' experience with preschool clinics has gradually extended habit training to the infant clinics and has also increased the upper age limit of infants to 4 years. "A progress chart of the infant's mental development and habit formation is kept from the 12th month to the 4th year; if any difficult problem arises the case is turned over to the preschool department for more intensive study." In the preschool clinic itself 70 per cent of the children are referred from the infant department.

An interesting and sound feature of these clinics is that habit problems are considered along with physical defects by the regular clinic staff, thus treating the child as an entity and not as a dissociated personality. Unusually difficult cases in the mental field are referred to the Child Guidance Clinic of the public schools. There is intensive follow-up of all cases in the homes.

Tables accompany this paper analyzing 400 consecutive cases attending the clinic. One of these "presenting the conditioning factors shows that, outside of 137 physical conditions, the majority of factors resided in the parents or environment, a potent argument for parental education." Most of the children were brought to the clinic because the parents felt there was a physical basis for their ills.

It is interesting to note that there are given as the most important two causes of failure in the clinic "poor coöperation on the part of the parents and failure of parents to improve even though they tried to coöperate."—From a paper given before the A. C. H. A. and A. P. H. A. Annual Meeting, 1928, by E. J. Huenekens, M.D.

Filling the Teeth of the Preschool Child—The national Congress of Parents and Teachers complains, according to the *Journal of the American Dental Association,* that parents of young children are unable in many instances to get dentists to attend to the deciduous teeth. This has come to light as a result of the summer round-up of children about to enter school for the first time in the fall. The dental journal's comment goes on to say that an examination of 1,087 second grade children in 40 different localities in Michigan showed that almost half of them had infected deciduous teeth.

A symposium is quoted dealing with the point in question. It demonstrates quite conclusively what stand is taken by various leaders in the dental profession. A few of the opinions expressed are quoted below:

C. J. Lyons, D.D.S., Professor of Oral Surgery, University of Michigan:

An old tradition that deciduous teeth under all conditions should be retained until their successors erupt is one that today is responsible for much illness among school children. Much greater harm will be done the little patient by leaving the infected tooth in the mouth at any age than will be done by extracting it. When caries in deciduous teeth has progressed to a point where fillings cannot be retained these teeth should be extracted regardless of the age of the child.

Harris R. C. Wilson, D.D.S., Director Cleveland School Dental Clinics:

The mesio distal dimensions of the bicuspids are completed at 5 or 6 years of age, if not

at 4; therefore these bicuspids are as large as they ever will be. . . . The problem of holding space with the temporary molars after 6 years of age is practically nil. At 3 years of age, I grant that the retention of the temporary molars is decidedly important; but even in this case, 3 years of age, I should not submit a child to the danger of serious infection from a non-vital temporary molar. . . . The old idea of holding space is obsolete in the mind of men who have had clinical experience of any considerable volume.

A. C. Thompson, D.D.S., Director Dental Service, Detroit Dept. of Health:

We find in our schools thousands of children with abscessed teeth due to lack of care. It has been our policy to remove every infected tooth that cannot be rendered free from infection. An abscessed temporary tooth uncared for is just as dangerous as an abscessed permanent tooth. Neither one should be tolerated.

From *Bull. Mich. State Dental Soc.*, Sept., 1928.

Dental Health Educational Materials—The old slogan "A Clean Tooth Never Decays" has done great harm in preventive dentistry, says William R. Davis, D.D.S., Director of the Bureau of Mouth Hygiene of the Michigan Department of Health. "This expression is true only for surgical cleanliness, and surgical cleanliness is impossible so far as we know in the mouth of a live person and not very important in a dead one.

"Many teeth that are brushed decay and many teeth that never saw a toothbrush never decay. No dentist on earth can make badly broken down and aching teeth as good as new. Why broadcast such teaching? Educational material that is not true or is out of focus should not be used, no matter how attractive.

"We have led many school boards and teachers to believe that toothbrush drills and cleaning teeth are the whole thing in a dental health program. In certain cases it will help prevent decay. Use of the toothbrush is a good habit, like taking a bath or washing the face. Twice a day, before going to bed and after breakfast, is a reasonable frequency to teach. Why teach five times, which is unreasonable? Why teach using gauze on the finger and boric or salt solution daily to wash the mouth of an infant which is correctly fed and in good health, when clinical experience shows that it does more harm than good?

"The two greatest factors in mouth hygiene are diet and early dental attention. It has been proved quite conclusively that wrong diet promotes decay and correct diet retards decay. If we could have early attention to small defects and correct diet, I believe we could almost wipe tooth troubles off the map even if another toothbrush was never manufactured. This may be rank heresy, but I believe research and clinical evidence are proving it."—From a paper given before the A. C. H. A. and A. P. H. A. Annual Meeting, 1928, by W. R. Davis, D.D.S.

Urologic Conditions Encountered in Children—Neglect of urological examination still being a not uncommon occurrence, this article is of interest and value. It is urged that the same thorough and complete urologic examination and study be made of the child presenting urinary symptoms as of the adult.

Children may be subject to "practically all the various urologic lesions which are encountered in adult life up to the fifth decade, though the symptoms and signs may in many cases be inaccurately described and entirely misleading."

Some pediatricians still hesitate to make a cystoscopic study, but with modern instruments perfected as they are, such examination is perfectly practicable.

In the series presented the youngest patient was 4½ months of age and cystoscopic examination, ureteral catheterization and functional kidney tests

were successfully made. Many patients received light ether anesthesia or nitrous oxide for the few minutes required to examine the bladder and urethra and to catheterize the ureters.

A *preliminary hypodermic injection* of morphine and atropine removes any inhibition of renal function from anesthesia. Cases cited in detail include retention, pyelitis, lithiasis, hydronephrosis, pyonephrosis, tuberculosis, congenital abnormalities and diverticulum of the bladder.

Pyuria and hematuria are noted, particularly as definite indications for early and complete urological study, and emphasis is laid on a belief that "early diagnosis and appropriate surgical treatment will, in most instances, prevent extensive and permanent renal injury."—B. A. Thomas, M.D., and J. C. Birdsall, M.D., *J. A. M. A.*, Nov. 10, 1928.

Training the Child's Emotions—Emotions determine the spice and flavor of life. But emotions, like all other functions of a growing body, must be trained for social living.

Children learn to control and develop their emotions by imitating the behavior about them in their homes, in school, on the playground and in the Sunday school. They respond to influences of their parents, of their reading, of the movies and theaters and of their observation of life.

The binding social force in the emotional life of the child arises from some sense of personal pleasure and satisfaction through accepting the standards of the family and the group to which he belongs. Emotions are related to some simple physical affairs, as, for example, consciousness of one's own size or strength or appearance. The emotional distress of a homely child or of an oversized child in a low grade sometimes beggars description.

The emotions are also bound up with the intellectual life. A high degree of intellectual activity may be a source of comfort and joy, while a limited capacity may give rise to sullenness, irritability and unpleasant school conduct.

The child's emotional reaction toward school is of primary importance. Every child should have some success in school. Even if the success is slight, praise and encouragement should always be given.

The child, however, is more than body and intellect. He is a part of the social world, subject to its laws and regulations. The pressure of social living causes strains within the child and the expression of these strains reveals the emotions that are entering into character. Hence the companionships of children, the mode of treatment by the adults about them, the behavior, the ideas, the sentiments and the practices of the parents profoundly affect the emotional life of the child, which involves his own happiness and that of his family and friends.—Ira S. Wile, M.D., *Hygeia*, Dec., 1928.

A Clinical Study of Enuresis—Any reliable addition to our present slight knowledge of causes and treatment of enuresis is always appreciated. In this study careful clinical analysis of the factors popularly supposed to be accountable for enuresis—relation of diseased tonsils and adenoids. eye strain, phimosis, vaginitis, pyelitis, posture, malnutrition or neurotic constitution—"failed to show their relation to this disease."

Cures, which amounted to about 80 per cent of this series of cases, "were accomplished without regard to any of these factors by measures directed to the bladder itself."

"The term 'enuresis vera' is suggested to indicate that type in which dissociation between the brain and the voluntary nervous system, as concerns the physiology of micturition, actually appears to exist, and the term 'pseudo-enuresis' is reserved for that type of defective control which can be relieved by measures designed to influence the will or to obtain the coöperation of the child."

The only measures found effective in the treatment of "true enuresis" were atropine and massage of the bladder.—Adrien Bleyer, M.D., *Am. J. Dis. Child.*, Nov., 1928.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

REPORT OF THE SUB-COMMITTEE ON NURSING OF COMMITTEE ON ADMINISTRATIVE PRACTICE *

IT seems advisable to go a little into the background of the committee's studies in nursing, in order to arrive at the reason for the present-day need of a sub-committee on nursing. In making the original appraisal form, the National Organization for Public Health Nursing was consulted at every step of the way about the place that nursing should take in organizations. Anne A. Stevens, R.N., who was then the Director of the N. O. P. H. N., gave a great deal of time to this. Nursing groups were apparently satisfied with the advice given and the conclusions reached.

Since that time, it has been nobody's job in particular to keep up to date on the appraisal or to advise in relation to its interpretation or evaluation. One of the reasons for the formation of such committees as ours was a growing feeling on the part of nursing groups that, when studies were made which involved nursing problems, some formal committee should be consulted in relation to conclusions arrived at and the recommendations made.

The N. O. P. H. N. is also making nursing studies and the volume of such studies is steadily increasing. It was considering an advisory committee to consult with its staff on field studies made. Consequently, with two groups making studies in the field the time seemed ripe to have a committee of each, which should function separately in relation to each group and jointly in regard to the relation of one group to another.

Naturally common problems would arise in relation to the scope of each group making studies; the kind of information to be gathered; the schedules for gathering such information; the evaluation of such studies; the conclusions and recommendations arrived at; and the coördination of one group to another.

The N. O. P. H. N. appointed a committee which is synonymous with our A. P. H. A. committee on nursing with one exception—the Director of the N. O. P. H. N. is a member of the A. P. H. A. committee, but is naturally not on the N. O. P. H. N. committee.

FUNCTION OF THE COMMITTEE

The function of a committee such as ours might be:

To assist in keeping the appraisal up to date

To assist in evaluating nursing services in relation to changing needs

To keep the field staff advised regarding general nursing trends and policies

To advise in relation to the extension of studies in nursing

To assist in working out some method of ascertaining qualitative as well as quantitative practice

To advise in relation to making specific studies

To be the medium of problems in relationship to the N. O. P. H. N.

To work out plans for coöperation and coördination with the N. O. P. H. N. in their nursing studies

Eventually, it is hoped that we may be able to work out some more definite

* Presented to the Committee on Administrative Practice of the American Public Health Association in New York, N. Y., May 24, 1928.

conclusions in regard to certain nursing practices and policies.

The committee has had one meeting as a whole with Dr. Walker, at which we discussed and reviewed the potentialities of the committee.

Dr. Walker met with the Advisory Committee of Field Studies of the N. O. P. H. N., at which meeting we reviewed their schedules for studies and also discussed some of the common problems, such as the extent of information it was advisable for the N. O. P. H. N. to give; the need of both the A. P. H. A. and the N. O. P. H. N. being in accord with relation to certain recommendations which they might make in relation to nursing studies.

SOPHIE C. NELSON, R.N., *Chairman*
MARY LAIRD, R.N.
AMELIA GRANT, R.N.
JANE C. ALLEN, R.N.

Annual Reports—"Annual reports can be roughly classified as surveys or obituaries," says the *Health News*. The better kind tells what has been accomplished and how this was done, and compares results so that contrasts between poorly done and well done health work show up clearly.

"In one sense an annual report should be like the record of a periodic health examination—designed to show up defects and to point out methods of prevention and cure."—*Health News*, New York State Dept. of Health, V: 47 (Nov. 19), 1928.

California Provides for Crippled Children—The Crippled Child Act of the 1927 legislature has been in operation less than a year. Due largely to the efforts of the California Society for Crippled Children, legislation was secured. It proved to be a timely measure, for an acute epidemic of poliomyelitis was more widely spread throughout the state in 1927 than ever before in history. While the Act has provided for all handicapped children, it is the sufferers from infantile paralysis who have benefitted from the provisions outlined in this Act.

The plan under which the law operates is outlined briefly in an article entitled "The Care of Crippled Children," in the November issue of *The Pacific Coast Journal of Nursing*.

Needy, physically defective or handicapped persons under eighteen years of age and residents of California who should have necessary surgical, medical, hospital, physiotherapy, occupational therapy or other service, special treatment, materials or appliances for use in relieving their defective or handicapped condition, may now obtain any or all of these at County expense under the provisions of the so-called "Crippled Child Act" of the 1927 legislature. Treatment is provided only for handicapped individuals, whose parents or guardians are unable to provide necessary treatment either wholly or in part.

It is the duty of the State Department of Public Health to furnish the necessary treatment and services upon presentation of a certificate from the parent or guardian stating that he is unable to furnish care.

The state does not bear the expense of the treatment, for all money expended under the authority of this certificate constitutes a legal charge against the county from which the certificate is issued.

Hospitals are opened to these patients and have local public diagnostic clinics. Health workers are generally informed regarding the times and places at which clinics and conferences are held.

A strict supervision over all cases under its care is maintained by the State Department of Public Health and, for this reason, a supervisor has been appointed. Visits are made and records are kept, so that improvements may be noted as they occur.

The State Department of Public Health is enabled by law to enter into agreements with parents and guardians to pay such amounts as they may be

able toward the cost of service, equipment and its transportation.

The law further empowers the State Department of Public Health to receive gifts, legacies and bequests to expend for the purposes outlined in the Act, provided no part of such funds shall be used for administrative purposes.

Counties are authorized to provide treatment independently for these cases or they may coöperate with the State Department of Public Health. A tremendous amount of good has been accomplished for the children of California as a result of the application of this law.

NOTE: According to reports, the Act in its present form is not entirely satisfactory. This is due, in part, to the number of patients requiring surgical treatment and also to the prolonged nature of the illness. Few counties could finance the program. It has been suggested that the expense be borne jointly by the county, state, service clubs, local welfare organizations and parents and guardians.

The matter of treatment of these cases brings up the problem of both scholastic and occupational education. The need for convalescent homes conveniently located and planned with an idea of giving necessary scientific treatment is already being demonstrated.

Until the program can be carried out along these constructive lines, full benefit will not be derived from the new law.—

Crippled Child Act, *Pacific Coast J. Nurs.*, Nov., 1928.

Permanent Responsibility versus Temporary—"What the Future Holds for Public Health Nursing under the American Red Cross" is discussed by Elizabeth G. Fox, R.N., in a recent pamphlet of that name. The first decade of the post-war nursing service is ending, and in the light of these past ten years Miss Fox raises the questions: "Where are we? Where do we want to be? How do we get there?"

The Red Cross is wholly or in part responsible for 568 public health nursing services, and is the largest single employer of rural nurses in the country. The rural field, however, is far from adequately covered; there is still great need for strong central promotion, guidance and support, such as the Red Cross, from its hard won experience, is well equipped to give.

Because of this, Miss Fox feels that the Red Cross should cease to consider its function as that of demonstrating public health nursing, and should adopt instead "an ideal of permanent responsibility for public health nursing in the community, and a policy of perpetuating partnership with public authorities."

This may be done by equal contribution of funds on the part of the chapter and the public agency, or by the official agency carrying the greater part of the expense while the chapter assumes the responsibility of administration. The Red Cross has much to contribute in experience, maintenance of standards, community interest and good will, as well as offering constructive program planning over a period of time, despite political upsets or changes of health officials.

With this ideal of long time responsibility on the part of the Red Cross for public health nursing activities, Miss Fox goes on to discuss problems which chapters will meet and lines along which they may well develop, touching on the need for nursing care of maternity and sick patients, prenatal supervision, the needs in counties of large area and small population, etc. Her conclusion shows the present position of the Red Cross Public Health Nursing Service:

It is ready now for its maturity; ready to put its hard-won experience to use in developing its services in accordance with growing demands and advancing standards; in pushing out experimentally into difficult fields; in seeking ways appropriate to the small town and village; of developing community nursing on a scale comparable with that in the cities.

L. A. D.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

The Big Idea for Minneapolis—The Cincinnati meeting of the Public Health Education Section was notable for the initial presentation of the diphtheria campaign. Chicago will be long remembered by many because of the two consecutive sessions on program planning. Before this paragraph is published the Section Council will have had a meeting to plan for Minneapolis, but an eager welcome is assured any suggestions for the "big idea" and for lesser ideas for the 1929 program of the Section. Address the chairman, Ira V. Hiscock, Yale University, New Haven, Conn.

Wherever There are Two or More—In any community or convention where there are as many as two people interested in some phase of health education-publicity there is the material for a get-together, formal or informal. From some of those who have been testing the idea comes the testimony that it is quite worth while simply to get together at luncheon now and then and chat over methods and problems. Merely "talking things over" may help a lot. The editor would like to hear of any groups getting together in any fashion.

Cross Word Puzzles—Questions and Answers—The Annual Directory of Newspaper Syndicates (*Editor and Publisher,* Aug. 25, 1928) lists 11 different syndicates selling cross word puzzles to newspapers. This fact and the very interesting "Do You Know" series appearing every Sunday in the *New York World* emphasize anew that these forms of publicity-education are by no means worn out. But when we adapt them to health and other social work they need to be well done.

Publicity Awards in June, 1929—Modest awards carrying great honors will be made for the best in news photographs, annual reports, radio talks, posters, feature stories, and Sunday magazine stories of 1928–1929. The awards will be made at San Francisco in June, 1929, by the Committee on Publicity Methods. A number of the 1928 awards were made to readers of this department.

A Popular Reference Book for Public Use—Make up a scrap-book or loose-leaf binder covering the patent medicines and undesirable remedies sold, advertised or known to be popular in your community. Get material from American Medical Association and other thoroughly reliable sources, securing two copies where material is on both sides of the sheet. Start each remedy at top of page and arrange in a b c order. When you announce the new book invite suggestions of remedies to include. Place on a shelf, with a big sign, where it can be consulted without asking for it. Tuberculosis societies and others might try this on their specialties. Something to be mentioned from time to time; usefulness not limited to the number actually consulting it. A committee of women might do the work of clipping and arranging the material. (Yes, this is a good idea. Let the scrap-book con-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

sist of newspaper clippings of patent medicine ads, with brief typewritten exposé under each. *Nostrums and Quackery*, published by the American Medical Association, will give information on many of them. Some years ago I prepared such a scrap-book for the Better Business Commission of Toledo with good result. A scrap-book might also be sent to newspaper editors, but be very tactful about it.—H. E. K.)

EXHIBITS

An exhibit of the Delaware County Tuberculosis Association: A wall map 4 by 5 feet, black and white outline with heavy lines for township and county boundaries. The 140 deaths, 1927, were indicated by

. . . 6 volt flashlight bulbs which are, I think, much more durable and take up less space than the bulbs that are commonly used in decoration. A transformer cuts the voltage down from 110 to 6. Bulbs representing deaths of negroes have been dipped in green Franco Print Lamp coloring. The bulbs representing deaths of white people we are allowing to remain white. Our first thought was to color these red but since we want to use the map in daylight as well as at night, we were afraid that the red lights would be too dim to attract much attention.—

Charles Kurtzhalz

STUNTS

And while we're on the subject of putting out fires, it occurs to us that the fire wagons and fire houses in every town and city in Indiana are the most important cynosures at least when some place is on fire. Why not ask the fire chief to carry a banner on the side of the fire wagons during December, where it'll make big publicity when there's a fire. The banner might say: "Put Out the Tuberculosis Fire with Christmas Seals!" And on the top of your traffic semaphores a great big Seal Sale sign could be implanted, urging those who pass the corners to "Drive Safely—Buy Christmas Seals!"—

Indiana Tuberculosis Association

The ship on the 1928 Christmas seal inspired a whole new line of stunts and more or less dramatic presentations of health and tuberculosis ideas. Mrs. W. H. Griffith, Sioux City, Ia., prepared several features in which music, readings, or dialogue provided new settings for old truths. All this emphasizes the possibilities in varying the form in which health facts and ideas may be offered and new angles of interest may be developed. History, news, personalities and other elements may be drawn upon for settings for health messages.

CLASSES

The most extensive course in health education-publicity yet available is that announced by the National Tuberculosis Association and Columbia University for January 14–26, which is open only to workers who have had some definite training or experience in publicity. Address the University, or Philip P. Jacobs, the conductor, National Tuberculosis Association, 370 Seventh Ave., New York, N. Y.

Also address Mr. Jacobs regarding the tuberculosis institutes, which include education-publicity sessions, to be held in Philadelphia, Pa. February 25–March 9), Columbus, O. (April 8–20), Minneapolis, Minn. (June 17–29), and probably Nashville, Tenn.

An evening course in educational publicity will be conducted (January 2–March 23) by the New York School of Social Work, intended primarily for executives and those doing publicity work. This, and the regular spring term course (March 25–June 15), will be conducted by Mr. and Mrs. Routzahn. Both of these courses call for much real work by the students.

TIMELY TOPICS

Colds, temperature, ventilation—an opportunity for very practical suggestions. The big task is to learn how to be convincing—how to get action! Most of our readers or hearers will agree to all that we offer—but will they adopt the suggestions?

One effort to "get under the skin" of the indifferent is the Syracuse "No-Cold Club." The "membership application and pledge" reads:

I want to be a Reg'lar Feller! Therefore, I solemnly promise to do my best to avoid colds, and will follow the By-Laws and rules of the No-Cold Club. I will also try to protect others from colds, and will tell others about the Club.

An illustrated 4-page folder gives the constitution and by-laws which bring out the anti-cold propaganda in unusual fashion. *It is not copyrighted.* Be sure to ask the Health Department or other health agency in Syracuse, N. Y., for a copy. The folder costs about $4.75 per 1,000 in 10,000 lots.

DATES AHEAD

Parents' Exposition, Grand Central Palace, New York, N. Y., February 23–March 2, 1929. Address: Parents' Exposition, 152 West 42d Street, New York, N. Y.

National Negro Health Week, March 31–April 7, 1929. Address: U. S. Public Health Service, Washington, D. C., or National Negro Health Week Committee, Tuskegee Institute, Ala. An opportunity for tuberculosis and other health agencies to serve as secretary or executive of state or local celebrations.

COÖPERATING GROUPS

Every community of any size contains numerous groups open to suggestions as to topics for papers, debates, discussions, reports and other forms of presentation. Boys' clubs, settlement clubs, school societies, debating clubs, men's Bible classes, church societies, and numerous others have programs of one type or another which should appeal to the ingenious health worker—not to offer speakers but to suggest ideas by which health material may be brought into their regular programs by their own members. College debating teams should not be out of our reach, and graduation essays are an easy possibility. Inter-settlement debates, speeches, etc., could be tried. *What have we done in any of these directions?* State and national health bodies might well tackle this job.

The revised Manual for Chapters (American Red Cross, Washington, D. C.) includes chapters on First Aid, Life Saving, Public Health Nursing, Home Hygiene and Care of the Sick, and Nutrition Service.

PUBLICITY DICTIONARY

Propaganda: "And publicity is propaganda, since it leads people who might be thinking of anything else in the world to concentrate on this one special thing for the moment."—Harrison Smith in "Do Book Reviews Sell Books?" *Atlantic Bookshelf,* May, 1928.

OFFICE

Ask *The Nation,* 20 Vesey St., New York, N. Y., for a copy of the green, hand-lettered renewal blank headed "Your subscription expires next month." Illustrates the distinctiveness of hand lettering—and colored paper—for small pieces of printed matter.

"Dictated but not read" still appears at the bottom of some letters. Such a letter says: "Here, old thing, is something I dashed off. It may not mean what it says, but it is up to you to decide what it does mean. It is not my responsibility." Why not return the letter with the endorsement "Received but not read"?

If you must write "Personal" or any other admonition to the one who opens mail it should be placed immediately above the address if you truly wish it to receive attention. My observation is that those who open mail do not look at the bottom of the envelope for special instructions.

But don't risk "Personal" unless it is personal. Writing on "Personal and Private" in *Printer's Ink* (Aug. 23,

1928), Amos Bradbury emphasizes "a growing practice among advertisers which is doing far more harm than good." The writer makes particular reference to the unfortunate use of "personal" on letters appealing for contributions.

The Milbank Memorial Fund, 29 Wall St., New York, N. Y., uses an effective printed address label for large envelopes and packages.

"The Vertifile" looks good for keeping cuts or plates from being scratched or lost. Harlo R. Grant and Co., 2322 West Madison St., Chicago, Ill.

To secure examples of how form letters, without individual addresses filled in, can be made effective in different sizes and shapes, ask for information and get on the mailing list by addressing Encyclopedia Britannica, 342 Madison Ave., New York, N. Y.

When you fail to get a reply to your letter asking for information or advice the simplest follow-up is a fresh copy of the original letter. This usually works, but sometimes a third or even a fourth copy needs to be sent when you are anxious for a reply. Letters do get lost in the mail—or in the office. And there may be good reasons for not getting off quickly a reply to your request. But to write and request a reply to your letter of a certain date may not help much. Suppose it was never received or has been mislaid!

CAMPAIGNS—SPECIAL DAYS

Early Diagnosis Campaign conducted by tuberculosis and other health agencies in March. Address any state tuberculosis association. The list of supplies, 23 items, includes folders, small pamphlets, 24-sheet billboard poster, smaller posters and cards, car cards, high school poster, gummed posterette, window display, lantern slides, strip film, motion pictures, electrotypes.

The Syracuse "No-Cold Club" is a feature of a campaign in which for newspaper publicity the Onondaga Health Association, Syracuse, N. Y., is enrolling the mayor, sorority girls, Rotarians, and other personalities, with quotations, interviews and radio talks.

A three-year campaign to secure "100 per cent sanitation" is under way in Virginia. Prizes are to be offered to the associations that secure the most improvements during the campaign. The slogan is "Virginia, the first state sanitated." A report of present conditions shows for each county the approximate number of homes, the percentage with proper sewage disposal, percentage with safe water supply and with adequate fly control. Rules of the contest and other helps are available through the State Department of Health.

NEWSPAPERS

"Of the news articles which yielded probably the largest number of clippings was one beginning 'A rheumatic twinge may not prophesy stormy weather,' declares Dr. Merrill M. Myers, president of the Iowa Heart Association, 'but . . .'"—*Annual Report of Iowa Tuberculosis Assn.*

That syndicates are selling 17 different daily or weekly health columns to the newspapers of the United States and Canada was revealed in Annual Directory of Features in *Editor and Publisher,* Times Bldg., New York, N. Y., Aug. 25. 90 cents. Eighty-three syndicates now offer nearly 2,000 different features to the newspapers, including 11 series of crossword puzzles!

The syndicated health columns are written by Dr. John Joseph Gaines, Dr. Logan Glendenning, Dr. Morris Fishbein, Dr. Herman N. Bundesen, Dr. Frank McCory, Dr. William Brady, Gorgas Memorial, Dr. Lulu Hunt Peters, Dinah Day, Jessie Knox, Dr. W. A. Evans, Dr. J. A. Jackson, Dr. J. W. Barton, and Paul J. Veatch.

BOOKS AND REPORTS

Public Health and Hygiene—*Edited by William Hallock Park, M.D. (2d ed. rev.) Philadelphia: Lea & Febiger,* 1928. 902 pp. Price, $9.00.

In the eight years which have elapsed since the publication of the first edition of this book, much has been added to our knowledge of public health, so that a second edition was most desirable. The present volume shows evidence of rewriting as well as careful revision.

Twenty-four authors have contributed to the present volume. The deaths of two of the original contributors, and the withdrawal of others, have made certain changes necessary. Additional chapters have been added on the control of cancer and the proper handling of patients suffering from contagious diseases, in order to prevent cross infections. Seven important subjects are treated by new writers.

There is little to criticise in the book. The individual chapters are complete in themselves and of high quality. The facts are not only correctly given, but the presentation is clear and understandable, an especially desirable feature, since the book is intended not for specialists in public health, but for physicians generally, and even students.

Because of advances which have been made during the past few years in our knowledge of foods, probably the most interesting chapters are those treating of this subject, and especially those on milk. In view of the increased use of dried milk, we wish that more than nine lines had been devoted to its consideration.

Some rearrangement is advisable, since septic sore throat, conjunctivitis, trachoma, tetanus, leprosy and mumps are included under infectious diseases of the respiratory tract. There may be some reason for placing leprosy and mumps in this category, as our knowledge concerning them is very incomplete, but certainly the others do not belong there.

The book is a distinct addition to one's library. The printing and make-up are exceptionally good.

M. P. RAVENEL

The Determination of Hydrogen Ions—*By W. Mansfield Clark, Ph.D. (3d ed.) Baltimore: Williams & Wilkins,* 1928. 717 pp. Price, $6.50.

The third edition of this work, which has become almost classic, especially in biological fields, is 50 per cent larger than the second edition and more than double the size of the first edition, though it has not become unwieldy. The increase in size is not due to haphazard additions. More than one part of the second edition has been critically curtailed in the revision, e.g. the bibliography has been cut from over 110 pages to about 80, covering the same range but with a more critical selection of titles.

A somewhat greater air of chemical sophistication appears in this edition due to the author's concept, in this revision, that it "is the function of this book to tell *about* a few of the more important matters in terms agreeing essentially with those which the reader will have to know in his study of the literature." Formal definitions of many such terms are made available in the appendix.

The author has succeeded, despite enough added material more than to justify the publishers' claims of "much new material and many new graphs," in keeping intact not only the general

structure of the book, with slight alterations in chapter order and numbering, but also the "more or less discoursive style," which has made each of the editions so readable.

The more obvious of the new material consists of: Chapter VII on The Application of Spectrophotometry, Colorimetry, etc.; Chapter XI on Changes of Free Energy; Chapter XVIII on Oxidation-reduction Potentials replacing the chapter on the Relation of the Hydrogen Electrode Potentials to Reduction Potentials; Chapters XIX and XX on a series of oxidation-reduction electrodes, the glass electrode, the oxygen electrode, etc.; Chapter XXII on Temperature Coefficients; Chapter XXV on The Theory of Debye and Hückel; Chapter XXVII on An Alternative Method of Formulating Acid-base Equilibria; and Chapters XXVIII and XXIX on Elementary Theory of Titration and Non-aqueous Solutions respectively.

These added chapters by no means exhaust the "new material." The older chapters have been very largely rewritten and much new matter incorporated, and the appendix, which has been greatly amplified, contains a fund of information.

The book can be recommended not only as a guide in matters of technic, but also as a store of subtle suggestion and an abundant source of information.

ALLEN E. STEARN

The Intelligent Woman's Guide to Socialism and Capitalism—*By Bernard Shaw. New York: Brentano's, 1928.* 495 pp. Price, $3.00.

The crafty pen of George Bernard Shaw will again give rise to dilatations upon the topics discussed, which, however, will soon lapse, because of the lack of adequate examples and statistics supporting most of his arguments concerning the seven proposed plans for the distribution of the country's income.

The book smacks a little of careful pigeonholing of past observations in order to revile effectively Capitalism as a background, in sharp contrast to Socialism painted in relief. It reminds one of the common fallacious belief that "If a small amount of medicine is good, an increased amount will be better." One misses the appreciation of the infinite varieties necessary not only for the "whole," but likewise the need of contrast for the individual. Consideration of the probable mode of transition from Capitalism to Socialism would add greatly to the value of the book. However, the author may claim that since the analysis has not been based on clean dissection, it should serve merely as provocative of thought, not decision. Too many statements take for granted the frequently absent capabilities and sense of proportion and values in individuals. The book is typically Shavian, stimulating to thinking and discussion.

M. P. RAVENEL

Physiology and Human Life—*By Robert A. Budington. Based on Advanced Physiology and Hygiene by Herbert A. Con and Robert A. Budington. New York: Silver, Burdett & Co., 1928.* 395 pp. (195 figs.) Price, $1.56.

This is a revision of an earlier widely used school text, bringing it up to date in the important fields of the endocrines, the rôle of the vitamins, and the effects of light upon tissues directly and upon metabolism. It also incorporates important advances in the knowledge and control of diseases made in recent years. The text has been entirely rewritten with emphasis upon the clearly established and well confirmed phases of these sciences. Each of the 22 chapters is supplemented by a list of readings in standard works and a list of questions designed to stimulate interest in the relations of the subject matter to the physiological facts of everyday life

and to disease in relation both to the individual and to public health. While the book is an admirable one with reference to its use in the discipline of education in scientific lines, it also has high value in inculcating in the reader an appreciation of the value of an intelligent and reasoned pursuit of good health. All public health workers will find in it a valuable work of reference for elementary use and an inspiring treatise in its point of view and purpose.

C. A. KOFOID

Social Work and the Training of Social Workers—*By Sydnor H. Walker. Chapel Hill, N. C.: University of North Carolina, 1928.* 238 pp. Price, $2.00.

The University of North Carolina Press has already issued a score of Social Studies ranging in price from $1.00 to $5.00, all of which should be in every social worker's library.

"No field of modern social concern," says the jacket of the present volume, "needs clear analysis or critical study more than social work. . . . Since Miss Walker is not a social worker and never has been one, her study happily lacks any semblance of special pleading and avoids narrowness—that occupational disease of the specialist."

If this were a column instead of a review, it might be amusing to consider whether the word "happily" should have been omitted in the quotation; and to discuss whether not being a social worker is really a guarantee against narrowness and the semblance of special pleading in a book which deals with social work and training for it.

However, this book is relatively free from such defects; and is the more readable because it seems to be written in the language of a student of education and economics with few of those special turns of thought and language which are so familiar in the conference papers, the periodicals and the textbooks of social work.

After preliminary chapters discussing the backgrounds, the characteristics and motives, and the objectives, of social work and the sources of its financial support, the author comes closer to her task in trying to discover what are really its characteristic activities and to interpret its claims. The eighth and ninth chapters set forth the educational needs of social workers, contrasting the prevalent apprenticeship with the specialized education now admitted to be essential, and then briefly but fairly describe the present professional schools and their courses. In the closing chapter Miss Walker discusses the very unsatisfactory existing relation between social work and the social sciences.

There are an extensive classified bibliography of over 30 pages and a directory of more than 50 periodicals in the field of social welfare and applied social science. EDWARD T. DEVINE

The Healers—*By B. Liber. New York: Rational Living, 1928.* 454 pp. Price, $3.00.

The healer who reads B. Liber's book will not find much comfort for his shortcomings whether he be regular or cultist. It might not do healers any harm to read the book; and health workers may well expect to profit by trying to understand the point of view of this biographical presentation of the trials and tribulations of an individual who, in attaining his medical degree, was not moulded into a standard product.

Paper, printing and literary style do not contribute to make the book easy or pleasant reading. Though it might be profitable reading for "healers," it is difficult to understand the place of such a book in general health literature.

ALEC N. THOMSON

Hunger Fighters—*By Paul de Kruif. New York: Harcourt, Brace, 1928.* 370 pp. Price, $3.00.

If the author of that interesting and successful book, *Microbe Hunters,* were contributing this review, he would probably say something like this: "The writer of that popular book, *Microbe Hunters,* has burst forth again to haul a bunch of bum scientists out of obscurity and tell the world their stuff in his customary and effusive style." And, despite a somewhat flatulent manner, he has told it, told it in 11 romantic short stories that hold the reader's interest from start to finish, even though there are times when the reader is forced to suspect that the romance runs away with the facts.

At the beginning of this engrossing volume the reader is given to understand that all of these heroes were completely forgotten until de Kruif honored them with his attention. This may be true of a few of his subjects, such as Carleton, the "wheat dreamer"; and it may be that the general public has never heard much about some of these workers, mostly governmental scientists; but certainly Mohler and Dorset, Babcock and Steenbock, Francis and Goldberger are well and favorably known in agricultural, public health, and general scientific circles. As a result of this book they will receive due recognition of their achievements.

Public health is indeed well represented in this group of stories about men who have contributed to human welfare, particularly in matters allied to food production. There are tales of the remarkable work on tularemia by Francis, the conquest of pellagra by Goldberger, the discovery of the principle of irradiation of foods by Steenbock, the development of genetic facts by Shull, the onslaught on hog cholera by Dorset, and the control of foot and mouth disease by Mohler. He has written a captivating book of narratives, as well worth perusal as those in *Microbe Hunters.*

The book is exceptionally well printed, with type that ought to delight the National Society for the Prevention of Blindness. It is competently illustrated by "Zadig." Read it by all means, for it is a fascinating volume.

JAMES A. TOBEY

Goiter Prevention and Thyroid Protection—*By Israel Bram, M.D. Philadelphia: F. A. Davis,* 1928. 327 pp. Price, $3.50.

The author discusses a subject of growing importance. The book has been written chiefly for the layman, though it is expected to be useful for the medical man as well. It is probable that more than 7 million people suffer from goiter in this country, in addition to which, Graves' disease, which the author considers a constitutional condition, influenced by the prevalent unrest and excitement of the general mode of living in this country, is taking an increasing toll of victims. Altogether, he considers that the thyroid gland is "more sinned against than sinning."

There is a good description of the thyroid, its functions in health, and the results of disturbed function. The chapter on endemic goiter is contributed by Dr. Olesen of the U. S. Public Health Service, and discusses its prevention by the use of iodine. The views of Dr. McCarrison on the relationship of iodine to goiter are also given, and we are warned against the promiscuous use of iodine and obesity cures, most of which contain thyroid extract. Especially dangerous is the taking of iodine in the exophthalmic form of the disease. There is a chapter on diet, which the author believes has a strong bearing on the structure and function of the thyroid gland.

While the book considers treatment, the author states that this is the busi-

ness of the physician, and those who feel that they are overweight should consult a physician before undertaking measures for reduction. Great stress is laid on relaxing and recreating forces, the chief of which he considers ". . . a healthy religion, sleep, music and laughter."

An appendix gives a brief description of the various ductless glands of the body and some history of our knowledge of endocrinology.

The material given is mostly sound, and there is much useful advice, though we believe that the endeavor to make a book for both the physician and the patient is a mistake.

The book is well printed and illustrated. M. P. RAVENEL

Physiology and Biochemistry of Bacteria. Vol. I—*By R. E. Buchanan and Ellis I. Fulmer. Baltimore: Williams & Wilkins, 1928.* 516 pp. Price, $7.50.

Progress in a science can often be best served by pausing to evaluate the disclosures of the past. Not only can the advances in the understanding of a specific subject be revealed by such a procedure, but a mere recounting of past discoveries serves to point the way to further advances and guards against following more or less seductive courses of action founded upon false premises. For a science presenting the phenomenal development of bacteriology such a pause for consideration of the validity of fundamental concepts is imperative, for, unless the facts keep within measurable distance of theory, the errors of the past become cumulative and fallacy will but lead to greater fallacy. It is gradually becoming evident that bacterial activity is not a thing wholly different and apart from other biological activities; that it is directed by and can only be explained by those laws recognized by the chemist and the physicist as governing biological phenomena in general.

Recognizing these things the authors of *Physiology and Biochemistry of Bacteria* have attempted to collect and evaluate the available information concerning the more fundamental properties of bacteria and the principles governing bacterial action. This they have done in admirable fashion, presenting a text that is worthy of the attention of all who are concerned with a study of any phase of bacteriology.

To record the sub-title of the book—Growth Phases, Composition and Biophysical Chemistry of Bacteria and their Environment, Energetics—states in the briefest possible way the content, but does not adequately express the diversity of the information presented. The enormous amount of work which has been done upon these basic subjects is impressive, and here, for the first time, may be found collected and interpreted those facts which future work in bacteriology must recognize. The recurring statement that more work should be done cannot fail to furnish the incentive for study in many directions, and serves to point out how incomplete our knowledge of many important phases of bacteriology is at present. Aside from its interest as an effort to deal with the more intimate phases of bacterial activity the text is readable and has great value as a reference book. The sub-title designates the book as Volume I. For the sake of bacteriology and bacteriologists it is to be hoped that other volumes will be forthcoming. GEORGE H. SMITH

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Tuberculosis Susceptibility and Humidity—High temperature and humidity did not alter the susceptibility and resistance of guinea pigs to tuberculosis.

BAETJER, A. M., and LANGE, L. B. The Effect of High Humidity and Moderately High Temperature on the Susceptibility and Resistance to Tuberculosis in Guinea Pigs. Am. J. Hyg. 8, 6: 935 (Nov.), 1928.

Venereal Disease Control—A general review of venereal disease control practice summarizing the work of one Canadian clinic.

BATES, G. The Venereal Disease Clinic. Pub. Health J. (Canada) 19, 10: 466 (Oct.), 1928.

Recognition of Juvenile Tuberculosis—A review of 300 preventorium cases which emphasizes the indefiniteness of physical signs and the importance of history. The need for preventoria for the observation of children is stressed.

BRONFIN, I. D. The Preventorium Child. Am. J. Dis. Child. 36, 5: 931 (Nov.), 1928.

More about Rheumatism—A symposium on rheumatism by foreign authors. The British medical press has been full of similar articles. The present series has the virtue of bringing the same material within easy reach of American readers.

CLARKE, J. T., et al. Symposium on Rheumatism. M. J. & Record 128, 9: 457 (Nov. 7), 1928.

Diphtheria Control—The difficulties of eradicating diphtheria in institutions by means of carrier finding procedures are stressed. Immunization with toxoid was found most effective in the naval school reported upon.

DUDLEY, S. F. The Control of Diphtheria in Crowded Institutions. Pub. Health (London) 42, 2: 1927 (Nov.), 1928.

Health Examinations and Cancer—The value of the periodic health audit is discussed and its particular importance in the detection of cancer is stressed.

FAUGHT, F. A. Health Examinations as a Means of Diagnosis in Cancer Control. M. J. & Record 128, 10: 515 (Nov. 21), 1928.

Skyshine and Rickets—White rats on a vitamin D deficient diet exposed to a north light behind Vitaglass had normal calcification of the bones whereas those behind ordinary glass developed marked rickets. Evidently skyshine provides ample antirachitic factor and direct sunlight an excess.

FLEMING, W. D. The Antirachitic Efficiency of Skyshine in Washington, D. C. Mil. Surgeon 63, 5: 658 (Nov.), 1928.

Child Care by Physicians—A summary of the points in child nurture with which the practicing physician should be familiar in order to guide the mother adequately. An excellent presentation.

GOLDBLOOM, A. The Rôle of the Physician in the Rearing of Children. New York State J. Med. 28, 21: 1274 (Nov. 1), 1928.

Phenol Soaps—Experiments are reported showing inhibitory action of soaps on phenol, indicating the uselessness of the latter in the production of germicidal soaps.

HAMPIL, B. The Effect of Pure Soaps on the Bactericidal Properties of Phenolic Germicides. J. Bact. 16, 5: 287 (Nov.), 1928.

Post-Sanatorium Care—How tuberculosis convalescents are brought back to productive life in a special work shop

is the story of this successful pioneering enterprise.

HOCHHAUSER, E. The Story of the Altro Work Shops. New England J. Med. 199, 19: 915 (Nov. 8), 1928.

Prenatal Hoarding of Antirachitic Vitamin—To test the validity of the assumption that the antirachitic factor is stored in the liver before birth, the potency of the factor in livers of premature and full-term infants was determined. No difference was found, which indicates that the predisposition of premature infants to the disease does not depend upon prenatal hoarding.

HESS, A. F., and WEINSTOCK, M. An Investigation of the Prenatal Factor in the Susceptibility of Infants to Rickets. Am. J. Dis. Child. 36, 5: 966 (Nov.), 1928.

Rickets Preventives—Cod liver oil in 5 mg. doses gives better protection to white rats against rickets than ultraviolet irradiation. Larger amounts of oil afforded no greater protection.

HOLMES, A. D., *et al.* A Comparison of Cod Liver Oil and Ultraviolet Light for Use in the Prevention of Rickets. Am. J. Dis. Child. 36, 5: 952 (Nov.), 1928.

Employment of the Tuberculous—A report on a successful experiment in medically supervised employment for 676 patients recovering from tuberculosis.

KLEIN, A. C., and THORBURN, G. Employment of the Tuberculous. N. Y. Tuberc. & Health Assn. Publication (Nov.), 1928.

Prevention of Human Rabies—Two deaths from rabies are reported in which the patients were bitten on the lip by known rabid dogs. Local treatment and Pasteur treatment (begun 3 and 4 days later) failed to prevent the disease. Immediate Pasteur treatment and cauterization with fuming nitric acid is urged.

RICE, T. B. Two Human Cases of Rabies. J. A. M. A. 91, 21: 1631 (Nov. 24), 1928.

Tuberculosis and Public Health—This Herman M. Biggs Memorial Lecture is a masterful and detailed presentation of the whole subject of health promotion and disease prevention. Too inclusive for summarization here.

KRAUSE, A. K. Tuberculosis and Public Health. Am. Rev. Tuberc., 18, 8: 271 (Sept.), 1928.

Health Work in Flood Area—Federal, State and non-official health agencies united to create in the Mississippi flood area 86 full-time county health units. A lasting blessing growing out of a great disaster.

LEACH, C. N. Progress of Health Work in the Mississippi Flood Area. J. A. M. A. 91, 21: 1595 (Nov. 24), 1928.

Per Capita Milk Consumption—A thorough house-to-house canvass of 18 southern communities revealed a higher per capita milk consumption among the whites than in the larger cities in the country. In these communities the daily consumption was 1.23 pints per capita.

LEACH, C. N., and FRANK, L. C. Milk Consumption in Eighteen Small Alabama Communities. Pub. Health Rep. 43, 45: 2955 (Nov. 18), 1928.

Maternal Mortality—A plea for better obstetrical practice by the family physician who makes 80 per cent of all deliveries. If lower maternal death rates are not secured in this way, State intervention threatens.

LITZENBERG, J. C. Obstetrics and Gynecology in Public Health Program. J. A. M. A. 91, 21: 1587 (Nov. 24), 1928

Prevalence of Venereal Diseases—A state-wide survey of cases of venereal disease under medical supervision made by the New York State Department of Health showed a prevalence rate of 4.57 per thousand. Many other interesting facts were revealed by the study.

PFEIFFER, A., and CUMMINGS, H. W. The Prevalence of Syphilis and Gonorrhea. New York State J. Med. 28, 19: 1147 (Oct. 1), 1928.

Etiology of Poliomyelitis—Streptococci recovered from the spinal fluid of fatal cases of poliomyelitis and experimentally inoculated monkeys were agglutinated specifically with hyperimmune poliomyelitis antistreptococcus serum.

ROSENAU, E. C. Streptococci in the Spinal Fluid in Acute Epidemic Poliomyelitis. J. A. M. A. 91, 21: 1595 (Nov. 24), 1928.

Carrier Infected Food—This is a report of an epidemiologic study of a typhoid fever outbreak found to be due to the consumption of corned beef infected by a carrier who prepared the meat for a church supper.

SCAMMAN, C. L., and FORSBECK, F. C. An Outbreak of Typhoid Fever Traced to Corned Beef Infected by a Carrier. New England J. Med. 199, 14: 664 (Oct. 4), 1928.

Scarlet Fever Prevention—The therapeutic and prophylactic use of anti-scarlet fever serum is questioned, but the use of toxin for immunization was successful in this author's experience.

TOOMEY, J. A. Treatment and Prevention of Scarlet Fever by Specific Antitoxins. J. A. M. A. 91, 21: 1599 (Nov. 24), 1928.

Biology of Senescence—The evolution and involution of human life is discussed in detail at the opening of Graduate Fortnight of the New York Academy of Medicine. A well drawn picture of the biology of life.

WARTHIN, A. S. The Pathology of the Aging Process. New York State J. Med. 28, 22: 1349 (Nov. 15), 1928.

Posters for Diabetics—Not only what to eat, but how to live, are the questions answered by this series of posters used to instruct diabetic patients.

WILLIAMS, J. R., and VYE, M. The Use of Posters as a Means of Instruction in a Diabetic Clinic. J. Lab. & Clin. Med., 14, 1: 57 (Oct.), 1928.

The National Tuberculosis Program—The program of the tuberculosis associations is on a sound basis and is one of the potent factors in the fall of the tuberculosis death rate. The individual objectives are discussed in convincing detail.

WILLIAMS, L. R. The Scientific Basis of the Program and the Accomplishments of the National Tuberculosis Program. Am. Rev. Tuberc., 18, 8: 249 (Sept.), 1928.

Cost of Nursing Service—A simple method of computing the cost of public health nursing visits is discussed. Although administrative costs are not allocated, the method is recommended because of its simplicity and value in determining costs of specific services, and relative amounts budgeted for each.

WINSLOW, EMMA A. Service Costs and Program Planning. Pub. Health Nurse 20, 11: 569 (Nov.), 1928.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Dental Clinic Services, New York, N. Y.—The dental clinic facilities now serving men, women and children of Greater New York who require free dental care or dental service at moderate costs are not adequate for the needs of this portion of the city's 6,000,000 population, according to a study just published in booklet form by the New York Tuberculosis and Health Association. In one district alone 20,000 school children whose teeth have been examined are waiting to have the necessary dental care done.

These and other significant facts are revealed in the report of a survey made by the association's Committee on Community Dental Service to bring to date a similar study made in 1923 and to review the dental clinic facilities of the city in terms of the community's needs. All the dental clinics in Greater New York, a total of 152, excluding those maintained and operated by specific industries for their employes only, were visited by a trained worker and the facilities and services were studied.

The study also discloses a tendency for dental clinic services to concentrate in Manhattan in spite of the trend of the population to other boroughs.

Since 1923, when the first survey was made, the clinics have increased from 104 to 152. Of the 56 new clinics established during the last 5 years, 35 clinics, or 65 per cent of the total, are in Manhattan. Twelve new clinics, or 21 per cent, are in Brooklyn; 5 clinics, or 9 per cent, in the Bronx; 3 clinics, or 5 per cent, in Richmond.

The study shows that most of the clinics serve only persons living in a specified area, members of a definite group of people such as club members in a settlement house, or patients within certain hospitals. Only one-fourth of the clinics serve the general patient.

Few of the clinics approach self-support, the survey reveals, but, in most cases, the fees charged enable them to be partially self-supporting. The fees vary from no charge in the case of 23 clinics to a fee of $1.50 for one clinic. The common admission fee, however, is $.25. Exclusive of all plant costs which include heat, light, rent and original equipment, the cost of dental care in clinics is estimated at between $3.00 and $3.50 an hour.

The Committee on Community Dental Service of the New York Tuberculosis and Health Association is planning this winter's program in view of the recommendations suggested by this survey. It is making a study of the population centers most in need of dental clinic facilities. It is attempting to interest the individuals and organizations of these districts in providing means to supply services where the need is greatest.

Los Angeles School District—School health officials will find interesting the 1926–27 report of the Department of Health and Corrective Physical Education of the Los Angeles City Schools. The department is divided into 30 sections and has a personnel of 315, including a medical director, 5 assistant directors, 30 physician inspectors, 29 physician consultants, 12 dentists, 62 nurse inspectors, 10 nurse teachers in high schools and 70 physical education teachers, among others. During the year 165,321 children were given physical examinations. According to the report children are examined upon entrance and at least every third year unless special defects require more constant supervision.

Every applicant seeking appointment

on the teaching staff of the city schools has had a careful examination as to physical fitness. A total of 2,550 teachers were examined during the year.

The corrective physical education section after 8 years of growth is able to reach approximately 50,000 children yearly with special care. All the senior and junior high schools have corrective rooms with teachers in charge. Since January, 1926, there have been 13 corrective physical education centers in operation to care for elementary children. From various schools children are sent with bad posture, flat feet, heart affections, nutrition disturbances and paralyses. Once a month an orthopedic specialist examines the most extreme cases of indigent paralytic children. The medical supervision of the examination is cared for by a special physician. It is also stated that 9,000 children with heart defects have been aided by this department.

"The value of nutrition classes is being realized as time advances and the work has had an opportunity to prove itself. Reports on improvement in school work, physical appearance, concentration, coöperation, disposition and general health have been received from the principals in schools where classes were conducted."

Open air sun rooms have been conducted in 10 schools. Eight health centers are utilized in addition to a Traveling Health Unit. The Parent-Teacher Associations coöperate fully in the school health program. The report concludes with a detailed statistical summary of defects found and corrected during the year.

LEAGUE OF NATIONS NEWS

C.-E. A. WINSLOW, DR. P. H.

Technical Conference on BCG—October 15–18, there was held in Paris a meeting of experts to draw up a program of international studies on the Calmette vaccine for tuberculosis. The conference included three special commissions, one of bacteriologists, one of clinicians, and one of veterinarians. The first of these commissions under the chairmanship of Professor Bordet of Brussels concluded that BCG* is a harmless vaccine which does not give rise to progressive tuberculosis, although Professor Nobel of Vienna maintained that in exceptional conditions BCG was capable of producing fatal tuberculosis in laboratory animals. The clinical conference concluded:

1. That BCG administered by mouth to infants within the first 10 days of life and by subcutaneous inoculation in other children and in adults is incapable of producing virulent tuberculosis lesions.

2. That vaccination by BCG produces a certain degree of immunity against tuberculosis.

The veterinary commission concluded that:

1. The experimental facts published and the unanimous opinion of practitioners who have used BCG in cattle justify the conclusions that vaccination carried out according to the technic of Calmette and Guérin, among bovines, is a perfectly harmless procedure.

2. Similar experimental data and published observations with regard to the use of BCG among bovines demonstrate that this strain of bacteria confers definite immunity against both experimental and natural tuberculosis infection. These recognized "pre-immunising" (prémunisantes) qualities justify and encourage the extension of the experimental use of BCG in the prevention of bovine tuberculosis.

* See p. 82 this issue, Editorial "The Calmette-Guérin Vaccine."

An extensive program of further study was recommended and this program has been approved by the Health Committee of the League. The Health Committee expressed no opinion in regard to the conference conclusions cited above.

Fall Meeting of the Health Committee—The Health Committee of the League of Nations held its fall meeting October 25–31, the United States being represented by Professor Alice Hamilton. The committee considered a request from the Council of the League that the health organization should "collect full statistical information regarding alcoholism considered as a consequence of the abuse of alcohol, giving prominence, *inter alia,* according to the data available, to the deleterious effects of the bad quality of the alcohols consumed." The Health Committee finally decided to ask the health administrations, at whose instance the Council's resolution was introduced, those of Finland, Poland, and Sweden, for more precise suggestions as to special lines of inquiry desired.

The Health Committee considered the reports of its malaria commission,* its permanent standards commission† and its special commissions dealing with infant mortality, cancer, and smallpox and vaccination. The infant mortality study is proceeding in a most encouraging manner with detailed inquiries cov-

* See p. 24 this issue, Editorial "A Report with Real Meat." *Pub. Health Rep.,* Nov. 9, 1928, p. 2957.

† *Pub. Health Rep.,* Nov. 9, 1928, p. 2957.

ering periods of 12 months in selected areas in 7 European countries. The cancer commission is at work on a comparison of the results of radiotherapy in cancer treatment, particularly in Munich, Paris and Stockholm. The smallpox and vaccination commission reviewed the evidence as to post-vaccinal encephalitis in England and the Netherlands, concluded that post-vaccinal encephalitis is a definite entity due to an independent virus which becomes active in persons vaccinated against smallpox, and pointed out that accidents of this kind do not occur in young children, emphasizing the importance of early primary vaccination.

The Health Committee has been invited to undertake a special study of dengue fever in southern Europe and to collaborate in a reorganization of the public health service of Greece, both of which enterprises will be undertaken in the near future.

NEWS FROM THE FIELD

CINCINNATI LAUNCHES A CAMPAIGN AGAINST DIPHTHERIA

THE Cincinnati Health Department under auspices of the Cincinnati Academy of Medicine has launched a campaign for the immunization of all preschool children against diphtheria. It is in this age group that 90 per cent of the diphtheria cases and 60 per cent of the diphtheria deaths occur. Parents are urged to take their children to the family physicians for toxin-antitoxin treatment. Free clinics have been established to provide treatment for those children whose parents are unable to pay for medical service.

OAKLAND IMMUNIZES ITS CHILDREN

THE City Health Department of Oakland, Calif., under direction of Dr. C. R. Fancher, City Health Officer, has begun a campaign for the immunization of all Oakland children against diphtheria and scarlet fever. No fee is charged for the treatment and there has been a most satisfactory response of children to be immunized.

CANADIAN HOSPITAL LIBRARIES CONDUCTED BY COLLEGE WOMEN

IN two hospitals of Montreal and Quebec, Can., libraries are managed and to a large extent financed by a committee of alumnae of McGill University, Montreal. This library program is the outgrowth of the libraries organized in 1917 for the military hospitals. The library in the military hospital at Ste. Anne de Bellevue has 5,236 volumes, and although this is a hospital caring mostly for mental cases the circulation last year was 6,615 books. The Royal Victoria Hospital for civilians contains 3,219 books and the circulation in 1928 was 23,114, an average of 74 books a day.

SCHICK AND DICK TEST OBLIGATORY AMONG MEXICAN SCHOOL CHILDREN

IN the government schools of Mexico the Schick test for diphtheria and the Dick test for scarlet fever are compulsory for all pupils coming within certain age limits and the tests and treatment administered upon recommendation are given by public health and school physicians.

GIFT OF $100,000 FOR CANCER TREATMENT

A GIFT of $100,000 was recently given to the Graduate School of Medicine, University of Pennsylvania, for the purchase of a gram of radium and other accessories for the treatment of cancer. The gift is from Louis J.

Kolb, of Germantown, Pa., a graduate of the University of Pennsylvania, class of 1887. The radium will cost about $72,000 and the balance of the gift will be used for cancer research. The fund will be known as the Louis J. Kolb Foundation for Treatment of Cancer. Dr. George E. Pfahler, professor of radiology and a former president of the American Roentgen Ray Society, will be in charge.

The university has also received a gift of $45,000 for cancer research from Irene duPont.

CHILD LABOR DAY

CHILD Labor Day will be observed January 26, 27 and 28 and the National Child Labor Committee under whose auspices this week has been inaugurated is asking the coöperation of schools, clubs, churches, private and public agencies to bring before the people of the country the problems of child labor so that public opinion eventually will be aroused to the complete abolition of child labor and universal legislation will be effected ruling against it.

OFFICERS OF MISSOURI CONFERENCE ON WATER PURIFICATION

AT the Fourth Annual Missouri Conference on Water Purification held at Hannibal, Mo., November 17, the following officers were elected: *Chairman*—C. E. Heflin, Water Commissioner, Cameron, Mo.; *Vice-Chairman*—S. J. Duncan, Superintendent Water Works, Moberly, Mo.; *Secretary-Treasurer*—H. D. Peters, Assistant Engineer, State Board of Health of Missouri; *Executive Committee*—W. V. Wier, Assistant Manager, St. Louis County Water Company, University City, Mo.; E. E. Wolfe, City Chemist, Hannibal, Mo.; W. P. Britain, Superintendent Water Works, West Plains, Mo.; J. N. Wells, Superintendent, Joplin Water Works Co., Joplin, Mo.

Among the several changes made in the constitution of the Conference was the change of the name to Missouri Water and Sewerage Conference in order to indicate the present scope of interest including municipal sewerage as well as water systems. Effort will be made for affiliation with the Conference of Sewage Works Associations. There was an attendance of 75 members.

DR. WILLIAMS RESIGNS AS NEW MEXICO COUNTY HEALTH OFFICER

DR. D. B. Williams, chief, Division of County Health Work, New Mexico State Bureau of Health, resigned January 1 after 6 years of service. The resignation of Dr. Williams was made necessary because of lack of funds to continue his salary and to meet the necessary traveling expenses. During his 6 years of service half of the expenses of this service was met by a grant from the Rockefeller Foundation, but the grant ceased January 1 and local funds were not available to carry on this county health program.

RASKOB MEMORIAL FOUNDATION TO AID NEEDY CHILDREN

THE Bill Raskob Foundation, incorporated with $1,000,000, has been established for the relief and assistance of needy children. The Foundation was established by John J. Raskob, chairman of the Democratic National Committee, in memory of his son, William Frederick Raskob, 2d, who was killed last fall in an automobile accident. Headquarters of the Foundation will be in Wilmington, Del.

DIRECTORY OF CITY HEALTH OFFICERS

A DIRECTORY for 1928 of health officers of cities of 10,000 or more population in the United States has been published in Volume 43, Number 46 of *Public Health Reports*, published by the U. S. Public Health Service, U. S.

Treasury Department. This has been published especially for the benefit of health officers and others interested or engaged in public health work. The data included in the directory have been furnished by the health officers of the cities. A directory of city health officers has been published by the U. S. Public Health Service each year since 1916.

HIGH RATE OF DEATHS FROM AUTOMOBILE ACCIDENTS

ACCORDING to an announcement made by the U. S. Department of Commerce, in the registration area of continental United States there were 21,160 accidental deaths in 1927 due to automobiles and other motor vehicles, excluding motorcycles, and the death rate from this cause was 19.5 per 1,000 population against 17.9 in 1926, 17 in 1925, 15.7 in 1924 and 14.9 in 1923.

The deaths assigned to automobile accidents do not include those due to collisions of automobiles with street cars and with railroad trains. In 1927 there were 476 deaths due to collisions of automobiles with street cars and 1,676 due to collisions with railroad trains.

REGISTRATION WORK IN NEW MEXICO AIDED BY ROCKEFELLER FOUNDATION

THE State Bureau of Public Health, New Mexico, has received an allotment of $200 a month for additional help on its birth and death registration program. The other agencies aiding New Mexico in its effort to get into the U. S. Registration Area are U. S. Bureau of the Census, U. S. Children's Bureau, and the American Public Health Association.

$204,400,000 GIVEN FOR HEALTH IN 1927

HEALTH activities received $204,400,000 from philanthropic donations during 1927. This sum was parceled out in the following sums: hospitals, $163,500,000; dispensaries, $9,600,000; public health nursing, $11,800,000; medical research, $13,000,000; health education, $6,500,000.

Education received $187,200,000; organized charitable relief in the United States, $256,700,000; play and recreation, $19,300,000; fine arts, $25,700,000; miscellaneous reform organizations, $13,000,000; religious purposes, $1,079,900,000; foreign relief including Armenia and the Near East, Austria, Poland, Germany, the Baltic States, Russia, Italy, the Balkans, China and Ireland, $214,500,000.

RACINE CHECKS UP HARD OF HEARING

IN Racine, Wis., recently the Board of Education requested the Board of Health to examine 40 children suspected of having difficulty with their hearing. The basis taken was 30 per cent disability. Examination showed that 13 of these pupils were over 30 per cent deaf in both ears; another 13 in one ear; 9 had loss of hearing in one or both ears of less than 30 per cent, and 5 had no actual loss of hearing, although some of them showed evidences of ear disease which if not checked might cause some degree of deafness.

Deafness was traced to diseased tonsils, enlarged adenoids; deafness following scarlet fever, measles, mastoid infections and influenza. Two children had badly constructed noses, and one suffered a running ear following an injury from a stone.

BIRTH REGISTRATION IN SANTA FE COUNTY, N. M.

SANTA Fe County, N. M., has been practically perfect in every check made on its birth and death registration. H. P. Mera, M.D., County Health Officer, attributes this to the close follow-up work and personal interest of his subregistrars. This explanation is made in the *Bulletin* of the New Mexico State Bureau of Public Health.

SIXTH SANITARIANS' SHORT SCHOOL OF TEXAS

AT the Sixth Sanitarians' Short School of Texas held early in November in San Antonio, 190 sanitarians were present. It was voted to hold the 1929 meeting in the lower Rio Grande Valley at Edinburg, Tex.

The following officers were elected: *President*—Dr. J. R. Mahone, whole-time county health officer, Edinburg; *First vice-president*—H. L. Darby, U. S. Department of Agriculture, Fort Worth; *Second vice-president*—Jack Wyatt, city chemist and director of sanitation, Amarillo; *Third vice-president*—Miss Delight Stone, supervising city health nurse, San Antonio; *Fourth vice-president*—Edgar Whedbee, assistant water supply engineer, Dallas; *Secretary-treasurer*—E. G. Eggert, sanitary engineer, State Department of Health, Austin.

WARNING AGAINST FRAUDULENT RAT EXTERMINATORS

EXPERT rat exterminators began a campaign among health officials and manufacturers during the summer in South Carolina, getting endorsement of the health officers, and money in advance of service in several instances from the manufacturers, but they failed to carry out their work against the rodents. This information comes to the *American Journal of Public Health and the Nation's Health* from Irving S. Barksdale, M.D., Commissioner of Health, Greenville, S. C.

The trio consisted of H. C. Noonan, T. H. Cooper and C. F. Hinman. The last named, however, did not appear in Greenville at any time. According to Dr. Barksdale the first two named came to Greenville with many references as to their ability and perseverance as rat exterminators. For two or three weeks after their arrival they apparently made an endeavor to render some service, but spent most of their time obtaining contracts and securing advance payments payable to the City Rat Campaign. This "City Rat Campaign" was unknown to Dr. Barksdale and unauthorized by him.

The exterminators baited several places, using, as some purchasers of the service estimate, about one dollar's worth of rat poison, and then disappeared very suddenly. Apparently they canvassed many cities of that southern area, obtaining contracts.

In making an exposé of the trio Dr. Barksdale has written to the Editor of the *American Journal of Public Health and the Nation's Health:* "I think you would render other health officials a great service if you would warn them against these self-styled expert rat exterminators. Their motives and methods seem very fraudulent."

DR. FRANCIS CONTRACTS MALTA FEVER

WHILE experimenting in his laboratory on the disease, Dr. Edward Francis, noted scientist of the U. S. Public Health Service and an authority on tularemia, contracted Malta fever recently. It is believed by laboratory associates that he acquired this cattle disease from cultures on which he had been working. Dr. Francis discovered that Malta fever is transmitted through milk of infected animals to human beings.

CALIFORNIA NURSES' HEADQUARTERS MOVE TO SACRAMENTO

THE Bureau of Registration of Nurses of the California State Department of Public Health, which has been located in the State Building, San Francisco, Calif., for several years, has moved to 405 Capitol Office Building, Sacramento.

All communications to this bureau should be addressed to P.O. Box 1159, Sacramento, Calif. The removal of the nurses' bureau to Sacramento is part of the reorganization of the state departments.

TRUCAS, N. M., TO CHECK SPREAD OF TYPHOID

UPON report that 7 cases of typhoid fever had developed at Trucas, N. M., J. I. Dunham, County Health Officer, immediately announced that the entire school population and at least 100 adults would be given typhoid vaccine injections, which means the inoculation of about 250 persons.

TEXAS WATER WORKS SCHOOL

THE Eleventh Texas Water Works School will be held January 14–25, 1929, at Bryan Agricultural and Mechanical College.

The school will be divided into several sections, including an elementary course in water works and sewage plant operation and sanitation.

DR. RECTOR GOES TO CHICAGO MEDICAL SOCIETY

FRANK L. Rector, M.D., Fellow A. P. H. A., formerly editor of *The Nation's Health*, and a member of the Chicago Medical Society, has been engaged as executive secretary of the Chicago Medical Society. Dr. Rector has just completed a report of a survey of health and hospital work in state and federal prisons.

PERSONALS

EMILY B. HEARD, R.N., has been appointed by the New Mexico State Bureau of Health as a field nurse under the Sheppard-Towner program for improving birth and death registration in the state. Her first assignment will be Otero County, N. M. Miss Heard has been engaged in public health nursing in Tennessee and Virginia.

DR. THURSTON W. LARAWAY is the new Health Officer of Elk River, Ida.

DR. C. M. BURCHFIEL has been appointed County Health Officer of Santa Clara County, Calif., by the board of supervisors to succeed the late Dr. William Simpson.

DR. H. B. EHLE, Health Officer of Lassen County, Calif., died in San Jose in October.

MRS. BEULAH M. KEITH has been appointed City Health Officer of Beaumont, Riverside County, Calif., to succeed Miss Beaunes Anderson.

DR. A. M. BURT, Health Officer of Ballston Lake, N. Y., died October 27.

Our National Accident Problem*

CHARLES B. SCOTT

President, Bureau of Safety, Chicago, Ill.

IT was estimated that in the year 1927 there were 95,500 persons killed in accidents in the United States, an increase of 4 per cent over 1926. If the increase this year is as great, the number for 1928 will be almost 100,000. The probable loss of 100,000 lives in accidents in one year certainly constitutes an important national problem.

Its importance is emphasized by a comparison with other causes of death. U. S. Bureau of the Census figures for 1926 indicate that in that year there were only 6 diseases with higher death rates than the rate for accidents. These were heart disease, pneumonia, nephritis, cancer, tuberculosis, and cerebral hemorrhage. For men only the importance of accidents is even more striking. In the year 1926 there were only 2 diseases among men which caused more deaths than were caused by accidents. These were heart disease and pneumonia. For women only, accidents stand 7th in importance among the various causes of death.

We have not sufficient information to classify accurately these 95,500 fatalities in accordance with the place where the accident occurred. We do know quite definitely, however, that about 25,800 of them were the result of automobile accidents. This is an increase of 1,050 per cent in number of deaths since 1911, and an increase of 400 per cent in the death rate per 100,000 population since 1913. This information on automobile deaths is made available through the records of the U. S. Bureau of the Census. But to what are the remaining 70,000 deaths due? In addition to these motor vehicle accidents there are several other main groups of accidents on which our information is less complete. There are in addition to motor vehicle acci-

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

dents other accidents that occur in public places but where a motor vehicle is not involved. In addition there are accidents occurring in industry and in homes. By a process which necessarily includes a great deal of guess work, statisticians of the National Safety Council estimate that about 25,000 of these 70,000 deaths occur in home accidents, another 25,000 in industrial accidents, and the remaining 19,700 in public (not motor vehicle) accidents.

The seriousness of our accident problem is emphasized by a comparison with those in other countries. Whereas the death rate from accidents in this country in 1926, according to the U. S. Bureau of the Census reports, was 78.6, the accidental death rate in England and Wales was only 35.6, in Scotland 44.9, and in New Zealand 52.3. These are the only foreign rates available but I am sure that if the records of other countries were before us we should find the United States well in the lead on the question of accidents as a cause of death.

Some interesting changes have occurred in accidental death rates over a period of years. In 1913, which is ordinarily taken as a normal pre-war year, the death rate from accidents was 85.5 per 100,000 population. This may be contrasted with the 80.5 per 100,000 in 1927, which is a drop of 6 per cent. The decrease has not been a consistent one, however, there being a gradual decline up to 1921 when the accidental death rate was 68.7 and an increase since that time. The decrease from 1913 to 1921 was 20 per cent and the increase from 1921 to 1927, 17 per cent. If the accidental death rate in 1927 had been as high as in 1913 there would have been 101,400 lives lost in accidents last year, or 5,900 more than the actual loss. If, however, the 1927 rate had been as low as that of 1921 the loss would have been only 81,500, 14,000 less than actually met death in this way.

The death rates from accidental causes are by no means uniform in the various age groups. Children are particularly subject to the hazards of accidents. On the basis of U. S. Bureau of the Census data there are only 2 diseases which cause more deaths among children from 1 to 4 years of age than accidents. These are bronchial pneumonia, and diarrhea and enteritis. Between the ages 5 and 14 years the situation is even more severe, for we find that accidents cause more deaths than does any disease. No one will deny that tuberculosis takes a heavy toll of lives between the ages 10 and 20 years and yet we find that in the first half of this period accidents cause twice as many deaths as tuberculosis, and in the second half two-thirds as many deaths as tuberculosis. These figures prove beyond any doubt that the national accident problem is indeed a serious one.

Organized safety work began in industry. The National Safety

Council was formed by industrial people who realized the importance of accidents both in their own plants and to society as a whole. Over the last 15 years interest in accident prevention work has extended to every phase of our national life, and therefore the scope of the council's activity has accordingly broadened. Throughout all this development it has again and again been proved that effective accident prevention work must be based upon complete data relative to accident causes. This is strikingly true in the industrial accident field, in which I have had most of my personal experience in accident prevention work. May I mention just one experience?

Very complete records of accidents that were kept under my supervision of safety work in certain public utilities indicated that, over a period of years, only 7 per cent of the accidents were charged to electricity. On the face of it this would not seem to be outstandingly important among all causes of accidents. However, further investigation of the records showed that these same accidents, while they amounted to but 7 per cent of the total number of accidents, resulted in 75 per cent of the total number of fatalities. This was clear evidence of the importance of the electrical hazard, and of the necessity for more stringent requirements to combat it. This is mentioned to show that detailed information on the circumstances and causes of accidents should form the basis of effective prevention work.

We are not sure how rapidly the industrial accident problem is being solved, because complete data on the subject are not available. We do know that in many instances industrial firms by careful analysis of their accident records, and persistent application of safety methods, have produced amazingly fine results. But at the very best the only information about accidents that can be obtained by industries will relate to industrial accidents only, and as a matter of fact it is only in industries covered by compensation laws that we have gotten very far along this line. We need data on industrial accidents that are not covered by compensation laws and we need data on the other 70,000 fatalities each year.

DISCUSSION

W. THURBER FALES, FELLOW A. P. H. A.

State Registrar, State Board of Health, Montgomery, Ala.

THE ever increasing toll in life and economic loss of accidents in this country demands attention not only of bureaus of safety, traffic managers, and factory superintendents, but demands the serious attention of the health authorities of America. Accident prevention requires the attention of health authorities because

deaths by accident form a considerable portion of the total death rate. In 1910 the death rate from the 5 infectious diseases, typhoid fever, measles, scarlet fever, whooping cough and diphtheria, was 80.2 and the death rate from all accidental deaths (homicides and suicides exclusive) was 84.4. In 1926 the corresponding rates were 35.6 for the 5 infectious diseases and 78.6 for total accidents. In 1910 typhoid fever death rate was 23.5, and that from automobile accidents was 1.8; the rates for 1926, of 6.5 and 17.9 respectively, show that the saving in lives from reduction of typhoid fever has been nearly counterbalanced by the increase in the deaths from automobile accidents. In other words, we saved 17 lives from typhoid fever in each 100,000 population and lost 16 additional lives through fatal automobile accidents.

Further, the large number of children who lose their lives daily through preventable accidents moves all who are interested in the conservation of child life. For example, 27.1 per cent of accidental deaths in Alabama are of children under 15 years of age, 19.3 per cent of fatal automobile accidents and 57.5 per cent of accidental burns.

Before a constructive and educational program for accident prevention can be carried out, we agree with Mr. Scott that more facts concerning the incidence of and circumstances under which accidents occur must be had. We all recognize the inadequacy of the classification of accidental deaths of the International List. Radical changes in this classification are not to be expected, and perhaps justifiably so if comparability with our past statistics on fatal accidents is to be preserved. Further, the enlargement of the death certificate to furnish additional information is out of the question. Therefore, additional information must be secured through some form of supplemental report.

It should be remembered that the supplemental report must be simple and that in most instances, for the present at least, it must be filled out through the voluntary coöperation of registrars, coroners, undertakers and others. Our daily querying of death certificates shows that doctors, registrars and undertakers will answer supplemental questions if pertinent to the case.

During the last couple of years Miss Hawley, my assistant, has queried all deaths from burns in order to secure information as to cause. This information has been valuable especially in showing the tremendous importance of unprotected fireplaces in this particular problem.

At the meeting of the Public Accident Statistics Section of the National Safety Congress in New York, October 2, 1928, Dr. DePorte proposed a very simple form for use by state registration offices. This form appears entirely practicable. Alabama purposes using a similar form, modified in unimportant details, next year to secure supplemental data concerning fatal accidents. We hope that many states represented at this meeting will undertake the securing of additional information in case of fatal accidents and I believe that for the present the National Safety Council would be the logical agency to correlate the reports from the various states on this problem.

The Biochemical Oxidation of Phenolic Wastes*

F. W. MOHLMAN, PH. D.

Chief Chemist, The Sanitary District of Chicago, Chicago, Ill.

THE biochemical oxidation of phenolic wastes mixed with sewage undoubtedly appeals strongly to the manufacturer, since this method of disposal is very convenient and of low cost from his standpoint. Before recommending such a method of disposal it is desirable to have considerably more information than we now have concerning the effect of these wastes on the rates of treatment of sewage on trickling filters and in the activated sludge process. Ammonia-still wastes contain organic solids which affect materially the character and composition of sewage. Increase in concentration of sewage requires larger acreage of trickling filters or increased aeration period and air consumption in the activated sludge process. It is conceivable that increased cost of operation of the sewage works receiving such wastes might be far greater than the cost of treating the wastes at the by-products coke plant.

Phenolic wastes are produced in two by-products coke plants in South Chicago, namely the By-Products Coke Company and the Wisconsin Steel Company.[1] A third plant, a subsidiary of the Youngstown Sheet and Tube Company, started operation in October, 1928. This plant is directly at the mouth of the Calumet River, a short distance from the 68th Street intake of the Chicago water supply. It would be quite unsafe to discharge ammonia-still wastes into the river or the lake at the Youngstown plant; consequently, studies have been made by the Sanitary District of Chicago concerning the practicability of discharging these wastes into the intercepting sewer tributary to the Calumet Sewage Treatment Works. In connection with these studies research has been carried on in the laboratories of the Sanitary District on the general subject of phenol wastes in sewage. This paper deals with some of the results of these studies.

In our main laboratory increasing concentrations of ammonia-still wastes were added to samples of settled sewage from Des Plaines Treatment Works, which is of average strength and contains no indus-

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

trial wastes. The effect of the wastes on the results of various chemical or biochemical determinations is shown in Table I.

The ammonia-still waste used contained 2,886 p.p.m. phenol. One per cent therefore added 28.9 p.p.m. phenol to the sewage. The maximum amount of waste added was 3 per cent, equivalent to 86.7 p.p.m. phenol.

It will be noted that the increase of ammonia nitrogen was negligible, but of organic nitrogen quite considerable. The biochemical oxygen demand showed a very great increase, although not nearly so great in percentage of the original amount as the increase in the permanganate oxygen consumed. Suspended and total solids increased markedly. Alkalinity and pH increased slightly. Bacterial counts increased from 343,000 per c.c. in the sewage up to 880,000 in the 2 per cent sample, then decreased to 289,000 in the 3 per cent sample.

These analyses show clearly the very marked effect of one or two per cent of this waste on the biochemical oxygen demand of sewage. In Table II it is shown that the average B. O. D. equivalent of 1.0 p.p.m. phenol in ammonia-still wastes was 1.68 p.p.m. for the 5-day B. O. D. and 2.37 p.p.m. for the 10-day value. It happens that the

Oxygen Required for Complete Chemical Oxidation of Phenol

$$C_6H_5OH + 7O_2 = 6CO_2 + 3H_2O$$

$$94 : 224 = 1 : 2.38$$

latter factor is approximately equal to the chemical equivalent for the oxygen required for the complete oxidation of phenol to water and carbon dioxide. This is probably an empirical agreement inasmuch as the sulphocyanides and other organic compounds in the ammonia-still wastes also require oxygen, in addition to the phenols.

These oxygen relations indicate that the addition of even less than 2 per cent of ammonia-still wastes produces a relatively enormous increase in the biochemical oxygen demand.

The B. O. D. of the Imhoff effluent at the Calumet Treatment Works in 1927 was only 57 p.p.m.; the addition of 1.2 per cent of ammonia-still waste of the average concentration used in this test would double the B. O. D. The wastes from the Youngstown plant alone would add approximately 3 p.p.m. phenol and increase the B. O. D. by 5 p.p.m.; wastes from all three plants would add 17.0 p.p.m. phenol, increasing the B. O. D. by 28.0 p.p.m. It is apparent that before ammonia-still wastes should be permitted to be discharged into the sewers a careful study must be made of the increased cost of operation due to the presence of the wastes.

TOLERANCE OF SEWAGE FILTERS AND ACTIVATED SLUDGE FOR PHENOLIC WASTES

Sand Filters—In order to obtain information concerning the maximum amount of phenolic wastes permissible in sewage treated by biological processes, small-scale experiments were started at the Calumet Treatment Works in March, 1928. Six small intermittent sand filters were constructed in galvanized iron cans 1.13 ft. in diameter. The depth of sand was 3.0 ft., and the surface area of each 1.0 sq. ft. The first filter was used as a control and was dosed with settled sewage; the others were dosed with the same sewage containing increasing proportions of ammonia-still waste from the Wisconsin Steel Company which usually contained about 2.9 gm. phenol per liter. Each filter was dosed at the rate of 100,000 gallons per acre per day, applied in three applications per 24 hours. Composite samples of influents and effluents were analyzed twice per week. Average results for April and May, 1928, are given in Table III.

Study of the influent analyses of Table III shows the marked increase of B. O. D. when 1.0 or 2.0 per cent of waste was added—from 40 to 72 and 114 p.p.m. respectively. The addition of even 0.1 per cent waste produced a noticeable increase in the concentration of the influent.

Effluent analyses show that with 0.1 per cent waste there was no appreciable deterioration in the quality of the effluent; with 1.0 per

Effluent	2.4	1.5	0.9	7.6	1.6	746	15.0	0.9

cent waste a satisfactory effluent was obtained, although not as low in ammonia and organic nitrogen, B. O. D., or oxygen consumed as the control, but slightly higher in nitrate. When 2.0 per cent of waste was added, the effluent was decidedly inferior, with 10.6 p.p.m. combined ammonia plus organic nitrogen, only 2.6 p.p.m. nitrite plus nitrate nitrogen, and the excessive value of 31.0 p.p.m. for oxygen consumed. This was not the satisfactory effluent that should be produced by an intermittent sand filter in good condition. The 10 per cent dilution of wastes gave a totally unsatisfactory effluent. The last filter, treating wastes from all plants in the proportions as produced, compared with Calumet sewage, gave a satisfactory effluent.

These results demonstrated that it is possible to handle influents containing up to somewhere between 25 and 35 p.p.m. phenol without serious interference with the biology of intermittent sand filtration. Later tests indicated that it might be possible to reach the higher concentration.

These tests must be considered to be more or less qualitative and not authoritative with regard to accurate determination of the rates

of filtration that may be obtained on a large scale. There is no doubt that the rate would have to be reduced as the proportion of waste increases.

Activated Sludge—We have made no experiments with phenolic wastes and activated sludge. In order to be conclusive these should be made in an operating continuous-flow plant and should extend over a period of several months. A test of a week or two is not sufficient inasmuch as the large initial bulk of activated sludge will adsorb rather large amounts of the phenolic wastes during at least the first few days, and then later lose much of its adsorptive properties. The frequently quoted tests made at Milwaukee* in 1920 were hardly conclusive for this reason inasmuch as they extended over only 11 days, but notwithstanding the short time of the tests, the removal of phenols was so complete as to give assurance that the concentrations treated during the earlier days of the test could be handled indefinitely. It is unfortunate that the statement has been made so frequently that 2.0 per cent ammonia-still wastes were treated, since the concentration of the wastes was quite low, averaging only 0.78 gm. per liter as compared with the 2.5 to 3.0 gm. per liter usually found in wastes from the direct process. Throughout this paper the proportions have been expressed in actual concentrations of phenol in the sewage treated.

The Milwaukee results have been re-calculated as shown in Table IV. It will be noted that approximately 14.0 p.p.m. phenol was applied most of the time, increasing to 21, 30, 48 and 61 p.p.m. during the last four days of the test. Inspection of the bacterial results

* Seventh Annual Report, Milwaukee Sewage Commission, Aug. 31–Sept. 10, 1920.

shows a consistently higher count in the effluent from the sewage plus wastes than from sewage alone, the increase in the former becoming rather excessive when more than 29.5 p.p.m. of phenol was present.

Further data should be available from the Milwaukee plant since it has been in full-scale operation.

Experimental tests have recently been made at Waldenburg[3] near Breslau, in Silesia, Germany. A very small-scale activated sludge plant was operated for 5 weeks at the rate of 1 liter per second. Ammonia-still wastes were added to give a concentration of 9.1 p.p.m. phenol during the 1st week, 18.2 p.p.m. the 2d week, 27.3 the 3d week, 36.4 the 4th week and 45.5 the 5th week. The results indicated complete removal at least through the 4th week (36.4 p.p.m.), and no serious impairment of the quality of the effluent until the 5th week.

The Milwaukee and Waldenburg results indicate that the activated sludge process may be able to handle up to 30 or 40 p.p.m. phenol from ammonia-still wastes without serious impairment of the quality of the effluent. The increase of air consumption or aeration period required by this concentration of wastes has not been conclusively determined.

NATURE OF OXIDATION OF PHENOLIC WASTES—AEROBIC AND ANAEROBIC CONDITIONS

The biological destruction of phenol in ammonia-still wastes appears to be accomplished by obligate aërobes. Anaerobes seem to be unable to decompose the phenol, unless very long periods of contact are permitted.

As an example of this difference an experiment was made in which approximately 30 p.p.m. phenol in ammonia-still wastes was added to Calumet sewage. The sample was divided into two equal portions. One portion was aerated in a 2-gallon bottle, the other placed in tightly stoppered quart bottles. A sample was taken from each portion each day and analyzed for phenol. The reduction of the phenol in the aerated sample between the 2d and 3d day was remarkable, the phenol decreasing from 29.9 to 2.9 p.p.m. The anaerobic sample remained completely unchanged for 4 days. Indeed, Fowler[4] has reported no change under anaerobic conditions for 14 days, while even after 8 months a large proportion of the phenol originally present (100 p.p.m.) was unaffected.

In some recent tests of sludge digestion in our main laboratory, 250 p.p.m. phenol was added to fresh sewage solids. After 138 days' digestion at room temperature the phenol content had dropped to 13.7 p.p.m., indicating considerable loss.

The relative effect of phenol on aerobes and anaerobes has

quite recently been investigated by Scott[5] at Manhattan, Kan.

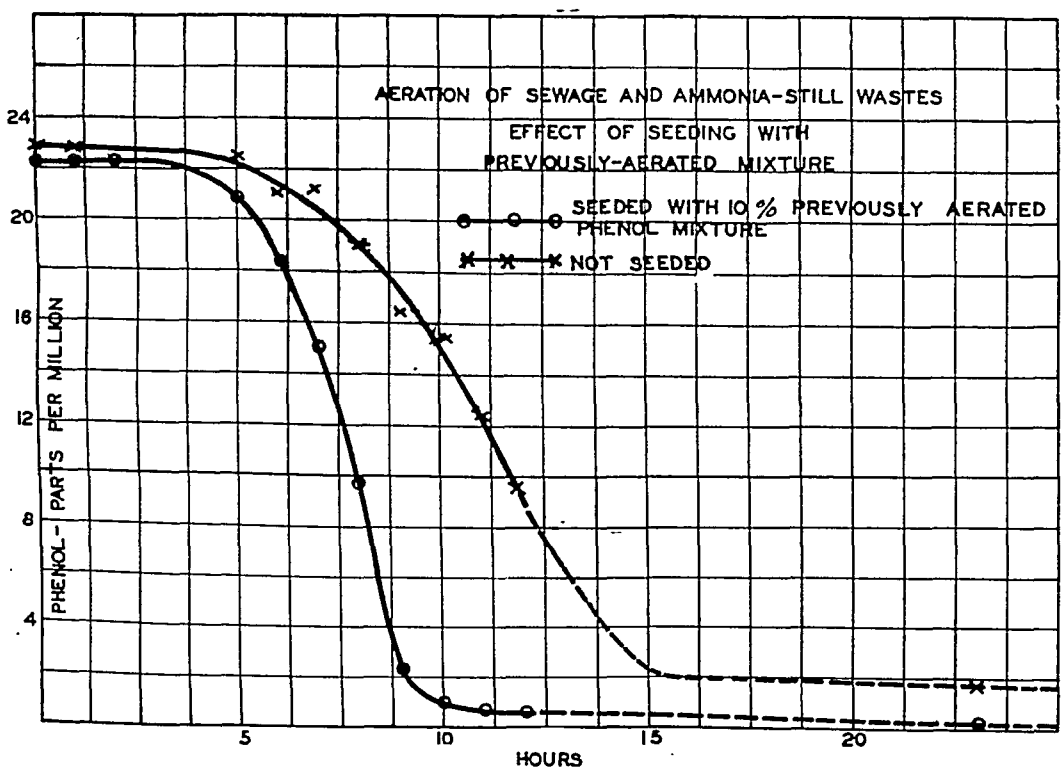
He exposed pure cultures of aerobes and anaerobes, growing in liver broth, to 0.5 per cent phenol. Sub-cultures were made after intervals up to one month. None of the anaerobic spore formers were destroyed in one month either at 37° C. or room temperature. Increasing the strength to 1.0 per cent phenol had no further effect. At 5.0 per cent phenol some anaerobes were sterilized in a few days but others survived for 10 days. Aerobic spore formers withstood 0.5 per cent phenol but not higher concentrations. Non-spore-forming anaerobes withstood 0.5 per cent but all non-spore-forming aerobes were killed at this concentration.

These observations indicate that anaerobes are in general far more resistant than aerobes. This confirms the fact that large concentrations of phenol are required before sludge digestion is inhibited seriously.

Effect of Re-inoculation—The biological filters that have been used by Fowler,[6] Bach,[7] and Brown[8] for the treatment of concentrated phenolic wastes depend upon the re-circulation of from 80 to 90 per cent of the filtered effluent for dilution and inoculation of the influent

FIGURE I

EFFECT OF RE-INOCULATION ON RATE OF BIOCHEMICAL OXIDATION OF PHENOLIC WASTES



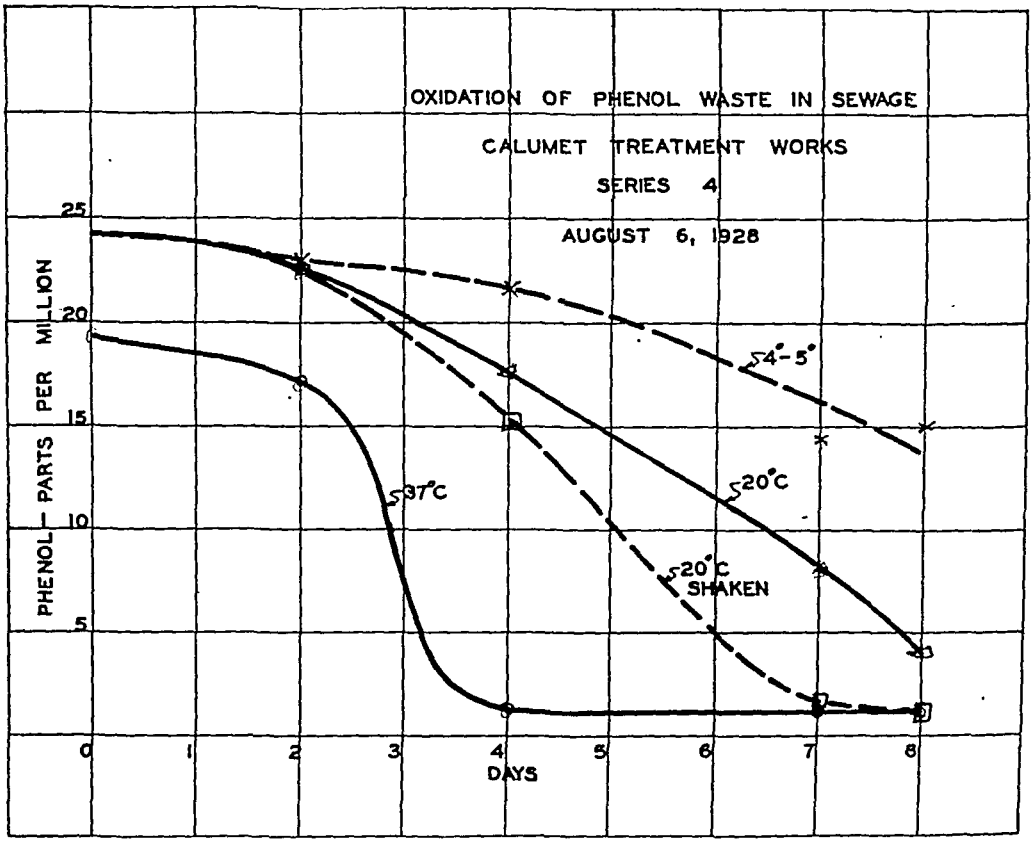


FIGURE II

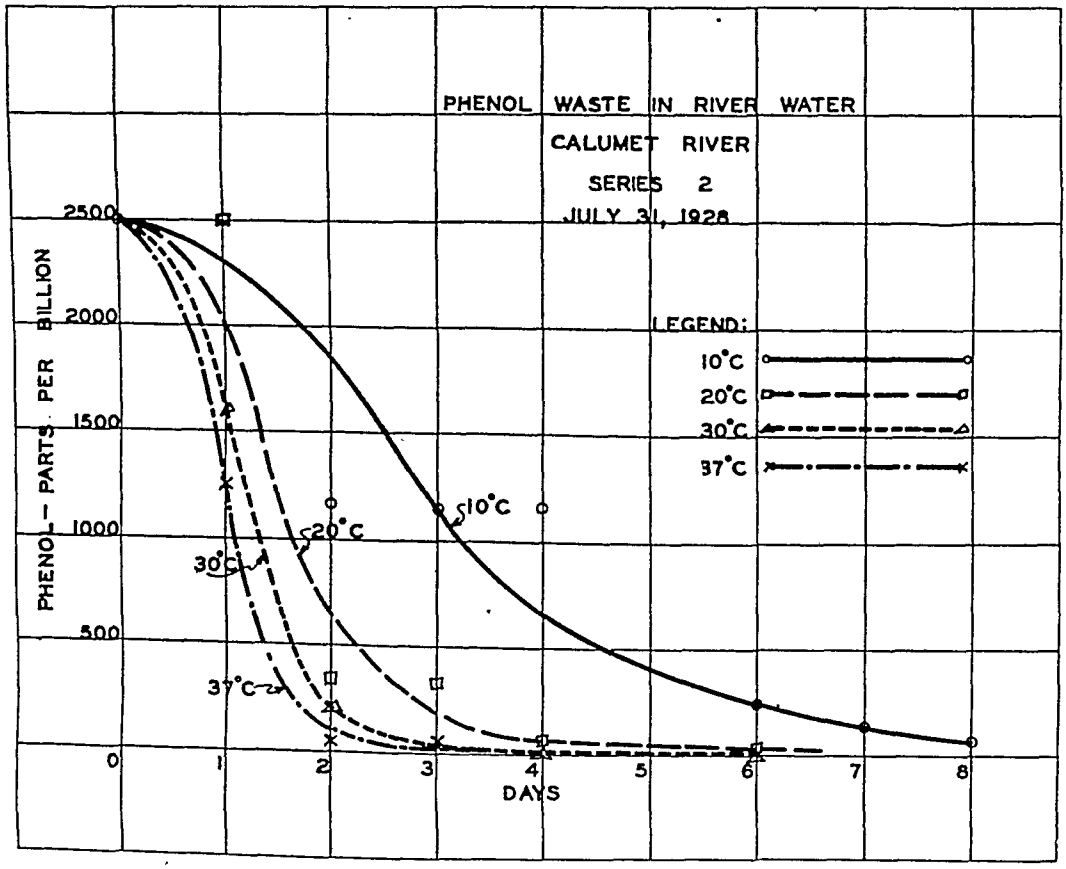
EFFECT OF TEMPERATURE ON RATE OF BIOCHEMICAL OXIDATION OF PHENOLIC WASTES IN SEWAGE

with organisms which have been "activated" or adapted to the oxidation of phenol. In order to show the value of this procedure a laboratory experiment was made by E. Hurwitz and S. Grant as follows:

Ammonia-still wastes were added to a sample of settled sewage from Des Plaines Treatment Works to give a concentration of about 25 p.p.m. The sample was aerated and samples withdrawn at intervals for determination of phenol. When the phenol had almost disappeared (after about 17 hours) 1 part of the effluent and 9 parts of fresh settled sewage were mixed for one portion of the test; the other consisted of a control of the settled sewage. Ammonia-still wastes were added to both portions to give 22 or 23 p.p.m. phenol. Both portions were then aerated with the same rate of air, and samples withdrawn hourly for phenol determination. The results are shown in Figure I.



The oxidation of the phenol was markedly accelerated by the presence of the 10 per cent inoculum from the previous aeration. The time of oxidation was reduced from 15 hours to 9 hours.

EFFECT OF TEMPERATURE

It is reasonable to assume that, within the limits of temperature suitable for bacterial life, an increase of temperature will accelerate the rate of oxidation of phenolic wastes. In order to prove this assumption two temperature-rate experiments were run, one in the Calumet laboratory by J. R. Palmer and J. I. Smith, and the other in the main laboratory by G. P. Edwards. The results are shown in Figures II and III.

FIGURE III

EFFECT OF TEMPERATURE ON RATE OF BIOCHEMICAL OXIDATION OF PHENOLIC WASTES IN RIVER WATER

Calumet sewage to which 20 to 25 p.p.m. phenol in ammonia-still wastes had been added was used in the first experiment. The rate of oxidation was greatly accelerated at higher temperatures. Not enough points on the curves were determined to warrant an attempt to calculate a temperature coefficient for the reaction.

Calumet River water was used in the second experiment. The phenol content was brought up to 2,500 parts per billion (2.5 p.p.m.) by the addition of ammonia-still wastes. Samples were incubated at

10°, 20°, 30° and 37° C. The difference between the rates at 10° and 20° C. is particularly noteworthy. At 20° C. the phenol content decreased to 100 p.p.b. in 3.4 days, while at 10° C. it required 7.4 days for it to decrease to this amount.

This fact has considerable practical significance and importance. It furnishes one reason, probably the most important one, why chlorphenol tastes are more prevalent in winter than in summer. Far more phenol is oxidized in the warmer water and consequently less of it reaches intake cribs. Further development should be made of this fact in specific instances.

METHODS OF ANALYSIS

Two methods of analysis for phenol have been used in these studies. For amounts ranging from 2 to 500 p.p.m. phenol the titrimetric method was used, as worked out by Williams.[9] Minute amounts of phenol in river water, ranging from 0 to 2,500 parts per billion, have been determined by the Gibbs[10] method, as modified by Baylis.[11] This is a colorimetric method which depends upon the color produced by phenol and 2.6-dibromoquinonechloroimide. This method is more specific than the Folin-Dennis or the Fox and Gage methods, but requires careful technic.

Palmer, E. Hurwitz, G. P. Edwards and their assistants for experimental work and the analytical results.

DISCUSSION

WILLIAM A. RYAN

Sanitary Chemist, Department of Public Works, Rochester, N. Y.

THE chemical composition of ammonia-still waste from the plant of the Rochester Gas & Electric Corporation is approximately as follows:

	Grams per Liter		Grams per Liter
Phenols	2.15	Thio-cyanates	0.15
Cyanides	0.15	Ferro-cyanates	1.98
Sulphides	0.19	Thio-sulphates	7.40

The first Rochester investigation to determine the effect of ammonia-still waste upon sanitary sewage was carried on in the City Laboratory with the assistance of Mr. Shnidman, chemist of the Rochester Gas & Electric Corporation.

The results of this investigation, carried out on a laboratory scale, indicated that ammonia-still waste added to the sewage in the proportion of 1 to 1,000 effected no change in the alkalinity, pH value or biochemical oxygen demand, and had slight effect upon the number or character of the bacteria normally present in the sewage. Little or no absorption of phenol could be detected during passage through the Imhoff tanks in which the detention period was one or two hours. A slight absorption of phenol resulted after 5 hours' contact with sanitary sewage, and approximately 75 per cent of the phenol was destroyed after a contact period of 72 hours.

Before granting permission to the gas company to dispose of the still waste by discharging into the sewer rather than into the Genesee River, the City Council thought it advisable to carry on further investigations on a plant scale to ascertain the effect of waste upon the sludge in the Imhoff tanks. These tests were carried on at the Charlotte plant, which has a flow of approximately 500,000 gallons per day and a detention period of 4 hours in the Imhoff tank. For a period of 10 weeks ammonia-still waste was introduced at the rate of 1 part to 1,000 parts of sewage. Approximately 8 feet of digested and well digesting sludge was present in the sludge compartment of the tank at the time the test was begun.

Conclusions drawn from the 10 weeks of operation are as follows:

1. The sludge formed was well digested and drained, and dried well upon the sludge beds.

2. The results of chemical analyses of the treated sludge showed no radical change except in the phenol content, which gradually increased until it reached a maximum of 12 p.p.m.

3. There was an increase in the bacterial count and in the amount of gas produced. There were indications that the addition of small amounts of phenol helped rather than harmed the digestion of the sludge.

For a period of 3 weeks, following the 10 weeks' test, the ratio of still waste to raw sewage was maintained at 1 to 166. A poorly digested sludge resulted which did not dry well. The safe ratio for adding still waste to sewage appeared to lie somewhere between 1 to 1,000 and 1 to 166.

As a result of this investigation, the gas company was granted permission to discharge the wastes from the ammonia stills into the sewer. For a period of a year, 360 pounds of phenol were daily discharged into the sewer and passed through

the 10 Imhoff tanks at the Irondequoit plant without in any way affecting the digestion of the sludge. The mean daily flow at this plant is 47.7 million gallons.

During January, 1928, four tests were carried on at the Brighton Sewage Treatment plant. This plant has both Imhoff tanks and trickling filters. The results obtained were as follows:

TABLE I

	Phenol Content in p.p.m.			Per Cent	Minimum
	Raw Sewage	p.p.m. Phenol Added by NH_3 Still Waste	Final Effluent	Phenol Absorbed	Temperature Degrees F.
A. Normal Sewage*	3.6		2.0	42.9	41
B. Sewage Plus Ammonia-Still Waste					
1. Ratio 1–850	4.6	2.0	3.1	31.1	41
2. Ratio 1–420	8.2	6.1	4.7	42.7	40.5
3. Ratio 1–210	11.1	8.6	7.2	35.1	41

* Average of 8 tests

It will be noted from Table I that, even at a temperature of 41° F., decomposition of phenol is possible by means of certain types of aerobic bacteria plus the oxygen present in the beds.

During the spring of 1928, an Emscher contact aerator was built in the Imhoff tank under construction at the Brighton plant. The tank and aerator were placed in service August 1, 1928. This test was carried on without the addition of ammonia-still waste. Previous tests indicated that phenolic compounds are normally found in sanitary sewage. Phenol was determined by the Folin-Dennis method.

Table II shows the average results of 12 analyses:

TABLE II

Date Collected	Phenol Content in p.p.m. Raw Sewage	Emscher Contact Aerator Effluent	Trickling Filter Effluent
9–15	2.1	2.8	1.8
9–17	3.0	2.5	1.9
9–20	2.2	1.6	1.1
9–21	2.3	2.6	1.5
9–22	2.8	3.2	1.9
9–24	3.8	3.8	2.7
9–25	2.7	2.4	1.5
9–26	2.5	2.4	1.7
9–27	2.0	2.0	1.4
9–28	2.3	2.5	1.8
9–29	1.8	1.8	1.5
10–1	2.9	2.2	1.8
Mean	2.53	2.57	1.72

Removal in Emscher Aerator—None
Removal in Trickling Filter—32 per cent
The temperature of the various samples averaged 62° F.

The results of these tests, taken in conjunction with the ones carried on in January, 1928, prove that the oxidation of phenolic wastes is not a purely chemical oxidation but one that must be accomplished through the assistance of certain types of aerobic bacteria.

Extension of Industrial Hygiene by Tuberculosis Associations in the United States*

BERNARD S. COLEMAN

Executive Secretary, Hudson County Tuberculosis League, Jersey City, N. J.

THERE are two primary reasons for including industrial work in a tuberculosis program: first, that tuberculosis is basically a problem of the working man and woman, since one out of every three or four deaths between the ages of 15 and 45 occurs from tuberculosis and the peak of our death rate is in the period of our greatest productivity; and second, that tuberculosis associations can most easily reach the tuberculous by organization of working men and women in the industries, since here we have some 40 million people in groups of various sizes who are much more easily approached than they would be as individuals."

A recent survey of the industrial hygiene activities of tuberculosis associations in the United States reveals some rather interesting facts. The majority of the larger associations include industrial hygiene in their program—from health education by health talks, motion pictures and the distribution of health literature, to the actual operation and supervision of medical departments in industrial establishments. For years attempts at industrial hygiene programs had been made, but with few exceptions the associations were handicapped by lack of funds or lack of proper personnel to carry the work to completion.

The survey which included a study of 69 state and local tuberculosis associations showed 10 conducting physical examinations in industrial plants. In some cases these examinations have been the forerunners of industrial medical departments in the plants. Six associations have developed placement bureaus to assist patients discharged from sanatoriums in securing employment. Twenty-six are endeavoring to interest employers and employes in individual health, factory sanitation, and other factors pertaining to industrial hygiene, by means of pamphlets, literature and posters; and conducting health talks and motion pictures in the plant during the noon hour. Fifteen coöperate

with the industrial establishments in their communities by serving as clearing houses for information on all matters pertaining to industrial hygiene, and assist them in solving health problems which may arise. Thirty-six associations are contemplating a program of industrial hygiene; 10 have made a survey of the existing industrial medical facilities in the plants in their communities; 1 has a tuberculosis advisory service, and another operates chest clinics in factories.

That industrial health is a tuberculosis problem was forcefully brought out by E. R. Hayhurst, M.D., in 1925 in the paper which he presented before the National Tuberculosis Association:

9. Evening clinics for labor unions

Tuberculosis exists to an unreasonable extent in the industrial group because of the ready lining up of a number of factors, such as unfit individuals for job placements, unfit jobs for individual placements, unfit surroundings for many jobs, unfit housing and recreational facilities in industrial communities, and unsupervised

sanitation and hygiene during the working hours. Industrial executives must believe in and patronize their own industrial medical services to beget the confidence of employes.

Dr. Hayhurst went further in voicing his belief that "Local tuberculosis societies might well take the leading part in stimulating the organization of medical and health supervision of industries and commercial establishments." Local, state, and county organizations are gradually awakening to their responsibilities along these lines and it is reasonable to assume that within the next decade a remarkable advance will have been made in the inclusion of industrial medical departments in plant management as a result of demonstrations conducted by the tuberculosis associations in various parts of the country.

That there was a large problem for tuberculosis associations to consider was evidenced in 1911 by the formation of the Committee on Factories of the Chicago Tuberculosis Institute, under the guidance of Dr. Theodore B. Sachs. A splendid program was developed, perhaps one of the most outstanding attempts at a comprehensive plan of industrial hygiene ever made in this country; it was carried along for 4 years and then unfortunately dropped. But in the meantime an excellent foundation had been laid for future industrial medical development in the plants in Chicago. The plan of this committee first laid emphasis on the search for tuberculosis among employes; but it soon became evident that the early detection of tuberculosis could best be accomplished through the general supervision of the employes' health, and thus it was concluded in the interest of economy that examination of employes for tuberculosis should be a part of a general industrial medical program.

Forty-one of the largest industrial concerns in Chicago and 14 social agencies coöperated with the committee; 24 conferences were held over a period of 4 years and at each meeting some important phase of industrial hygiene was discussed.

The committee's aim was:

> Toward detection and suppression of sources of infection in the working place; detection of cases of the disease in the curable stages; guidance of all employes predisposed to the disease and of those who are reëmployed after having recovered their health by sanatorium or home treatment; guidance of all employes in right living and methods of prevention.

It was considered the ultimate function of the Committee on Factories of the Chicago Tuberculosis Institute " to assist, whether by state insurance or other measures, in bringing about adequate protection for the employe, from sickness, invalidity, old age." Nor did the report fail to mention the extension and strengthening of employes' benefit associations and industrial insurance as well as the importance of " not relegating to the scrap heap " the physically handicapped.

As a result of the conferences held by the committee many of the larger firms adopted a program of medical supervision. At the beginning of the campaign there were 20,000 employes represented in the conferences; 30,000 were employed in plants where examinations were made of all suspicious cases of illness, but in none of them were examinations made of new employes. At the end of a 3-year period 187,100 were represented; 150,000 employes were in plants practicing examinations of all suspicious cases of illness; and there were 58,000 employed in plants requiring examination of all new employes. It had also been hoped to reach the smaller factories, but this was not accomplished during the 4-year period.

At about the same time that the Chicago plan was put into effect, other tuberculosis associations became interested in the fight against tuberculosis among working men's organizations in the United States, resulting in the formation of the Trades Union Section of the Buffalo Association for the Relief and Control of Tuberculosis and the Trades Union Anti-Tuberculosis Association of Newark. The latter is still active.

In a report published in 1916 by the National Association for the Study and Prevention of Tuberculosis, it was stated:

> The anti-tuberculosis society that fails to utilize the organized efforts of the workingmen is missing a real opportunity. No matter whether a community is strongly unionized or not, with a tactful approach and a proper plan, the men and women in the mills and factories can be turned into a mighty source of influence in their community, both for the good of the general public health and for the benefit of the individual personal hygiene of the workers themselves.

The report advocated periodic medical examinations to discover and control early cases of tuberculosis and other diseases and to provide for suitable employment of the convalescent worker. It directed attention to the responsibility of the tuberculosis associations in sponsoring a program of industrial hygiene.

During the last decade the most outstanding work in industrial medical development by tuberculosis societies has been that of the Philadelphia Tuberculosis and Health Council, under the leadership of Dr. Harvey Dee Brown. An industrial hygiene program has been sponsored and developed to demonstrate to industry the management and operation of the medical department in the plant proper and the advantages to be derived therefrom. The decision to include industrial hygiene in its program was inspired by Dr. Horwood's Tuberculosis Survey of Philadelphia in which he recommended that:

> . . . particular emphasis must be directed toward finding the early adult cases of tuberculosis, especially among those who are industrially employed, and to this end it is urged that . . . the anti-tuberculosis campaign be directly introduced

into the various industries, through the holding of clinics, the use of tuberculosis nurses, and the dissemination of knowledge concerning tuberculosis.

To the Philadelphia Tuberculosis and Health Council belongs the credit for showing other tuberculosis associations how the work can be done, and it is interesting to note that several are already following in the course outlined by the Council.

Beginning with noon-day talks, the distribution of posters and literature on health matters, and night clinics for industrial workers, a health examination service for employes of small plants was started. The interest of the employers was aroused and it was not very long before the service was being paid for by industry, whereas it had first been given by the Philadelphia Tuberculosis Council as a demonstration and without charge. With this development a survey was undertaken to determine how many plants in Philadelphia had medical service, and on the basis of this survey, which showed that the majority of the smaller plants had no medical service whatever, the Council undertook to present its Unit Plan for coöperative medical service among these plants.

In this plan units are made up of plants with less than 500 employes, reasonably near each other, and having a total of 1,000 employes for the unit. A full-time nurse and a part-time physician are necessary for each unit, and each plant sharing in the unit provides a clinic room at the plant. The cost for the maintenance of the unit is shared by the individual plants on a pro rata basis depending upon the number of employes. This amounts to $4.50 per employe per year. All organization and administration expenses, that is, cost of record forms, establishment of medical department, and organization of the work, are borne by the Health Council. Excellent results have been attained.

In 1927 the Council was successful in developing health work in 20 plants, in 4 of which the work was taken over and continued entirely by the plants. Industrial medical activity was supervised in 15 plants to the extent that the work can be taken over by the plants themselves whenever they are ready to do so. In Philadelphia 6,000 employes are now in plants in which there is medical supervision as a result of the efforts of the Council.

A report of the Council states that in 1927 there were 18,682 visits to plant dispensaries maintained under the Unit Plan. Of these 10,871 were for minor accidents and 7,811 for various slight accidents.

The Unit Plan includes a monthly health poster service, health classes among employes, advice on personal health problems, sanitary surveys and monthly sanitary inspection of the plant.

The Philadelphia experiment has led to the development of industrial hygiene programs in the activities of the tuberculosis associations of Paterson, Newark and Jersey City, N. J.; Erie, Chester, Bethlehem and Scranton, Pa.; Louisville, Ky.; and Indianapolis, Ind.

In Paterson, N. J., several plants have already taken over the work demonstrated by the Paterson Tuberculosis and Health League. Nutrition classes for underweight employes, in addition to the health examination service, and night clinics for labor unions have been established.

For the past 3 years the New Jersey Tuberculosis League has maintained an industrial health service intended to demonstrate to industry the importance of guarding the health of the worker, the value of periodic health examinations and the manner in which a program of medical supervision in the plant can be carried out systematically and efficiently. During this period 3,396 examinations were made in 30 plants in Newark. Sixty-four cases of tuberculosis were detected, of whom 27 were later admitted to sanatoriums, only to be returned to their jobs as arrested cases at the end of their stay. The examination service in Newark was intended to serve as the nucleus for the development of the Unit Plan.

The Hudson County (N. J.) Tuberculosis League has only recently started its health service for industry, and is patterning its program according to the Philadelphia plan, with slight modifications. A survey of industrial medical facilities in the county has been made and it shows a general lack of direct medical supervision in the industries, especially in those employing less than 1,000 employes. Here, as also in Newark, Paterson and Philadelphia, a demonstration of the physical examination of the employe will be made before the Unit Plan in part or in its entirety is offered to the plants. Great stress is being laid upon the physical examination of the applicant prior to placement; periodic examinations of all employes every year, except where otherwise indicated; "fitting the individual to the job"; the care and cleanliness of wash rooms, locker rooms, rest rooms and toilets; and proper illumination and ventilation in the plant. An effort is being made in the follow-up of all employes examined to have them correct their physical defects. In case of inability to pay for medical treatment the employes are directed to the clinics in the county. The follow-up work is considered one of the strongest points of the entire program, for by interesting the individual in his own physical condition it is hoped to further interest him in the betterment of conditions at the plant from the standpoint of hygiene and sanitation.

The Hudson County Tuberculosis League, in conjunction with the

Hudson County Safety Council, is planning a series of lectures on industrial hygiene to plant executives and foremen. These will include the health of the worker and sanitation of the plant. Matters pertaining to compensation for industrial accidents and diseases, and the medico-legal aspects of the latter will be discussed.

In Erie, Pa., a survey has been made, the demonstration of examinations is being carried out, and it is planned to develop the Unit Plan. The Erie Anti-Tuberculosis Society believes that under proper supervision, "it should be one of the most important services that a tuberculosis association can do for an industrial community." The interest and coöperation of the Erie Manufacturers' Association and the Erie Safety Council have been secured.

The New York Tuberculosis and Health Association maintains a Tuberculosis Advisory Service for the purpose of assisting industrial physicians and personnel directors with problems pertaining to the early diagnosis of tuberculosis and the placement of patients in different stages of the disease. The service was organized "at the suggestion of some of the well known industrial physicians who now make use of it and consider it part of their respective organizations, and is designed to assist in the care of such patients as are reluctant to consult a specialist because of the cost, yet whose position is such that they are unwilling to accept free care." Some of the largest industrial organizations in New York City are subscribers to this service.

In 1926 an industrial survey of Hartford, Conn., was made by the Hartford Tuberculosis and Public Health Society. It was conducted in 39 factories employing 25 or more persons each and covered a total number of 18,875 employes. The majority of the plants were members of the Hartford Manufacturers and Employers Association. As a result of the survey it was concluded that "the development of medical service is more practicable in the larger plants than in those employing fewer numbers, but that a joint plan of medical service could be adopted in a group of smaller plants."

The Marion County (Ind.) Tuberculosis Association has "extended its health efforts into Indianapolis industries with the hope of interesting employers in increased efficiency in industry through the systematic health supervision of employes," and has conducted physical examination campaigns and developed adult nutrition classes.

A county industrial health program has been developed by the Tuberculosis Society of Detroit and Wayne County, Mich., but it has not included the development of an intensive medical service in factories. The society acts as a clearing house for the tuberculosis problems arising in factories; it has an extensive program of health edu-

cation for industry; and maintains an employment service for arrested cases of tuberculosis.

In carrying on the fight against tuberculosis in industry many problems are presented pertaining to the health of the individual and of the public in general, and the physical examination clinic, sponsored by the majority of tuberculosis associations in the United States, can become the nucleus of an extensive industrial medical department.

CONCLUSION

This paper has purposely omitted a discussion of placement services, rehabilitation work, and the various types of educational work performed by the tuberculosis associations. It has aimed rather to summarize in a general way the extent to which industrial hygiene activities are being included in their programs. Considering the interest and work undertaken during the past few years it is reasonable to assume that definite progress, although slow, is being made in the extension of industrial hygiene by tuberculosis associations in the United States.

Many of the tuberculosis organizations studied in the survey are making an attempt to interest industrial executives in the advantages that may be derived from industrial medical service in the plant, and to date there have been many instances of success as a result of these endeavors.

A Series of Typhoid Fever Cases Infected per Rectum*

C. R. HERVEY, M. D., FELLOW A. P. H. A.

District State Health Officer, Oswego, N. Y.

DURING January and February, 1928, 13 cases of typhoid fever occurred in a group of surgical patients in a general hospital of 118 beds.

Transmission of the disease is attributed to the practice of using the same Harris drip apparatus interchangeably between patients without sterilization. The Harris drip apparatus consists of a container for fluid, and a rubber rectal tube. Unlike the Murphy drip, the Harris drip container is placed at the side of the patient at the level of the abdomen, and the fluid allowed to flow under very low pressure. As there are no check valves the containers are subject to gross contamination when a reverse flow occurs during vomiting, straining, or the advance of gas or feces in the bowel. At the time of the outbreak it had been the procedure to sterilize the tubing, but the containers were rinsed in tap water only.

The outbreak was explosive, or at least semi-explosive in character, all the cases occurring in a period of a little over 3 weeks. The age incidence ranged from 8 to 79 years, though only 3 of the cases were under 25 years of age.

With one exception the cases were confined to the second floor of the hospital, consisting of 17 rooms and a small ward of 4 beds. Four of the rooms contained 2 beds each, which were occupied at the time in question. In 9 of the rooms on this floor, and in 1 room on the first floor, typhoid cases occurred.

The onset of the first case was probably January 24, but the presence of typhoid was not suspected until February 5, when the third case in the series died, and an autopsy showed typhoid lesions. Following this, typhoid was demonstrated in all cases by laboratory tests of blood, urine, and stools.

All the cases had been on the Harris drip and, with one exception, occurred after surgical operations. The exception was a patient with carcinoma, who received the drip as a sustaining measure.

---

* Read at a Special Session on Epidemiology of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

The drip containers were not suspected until February 13, by which time 9 cases had developed. They were sterilized on this date. The onset of the last case was 6 days later, on February 19.

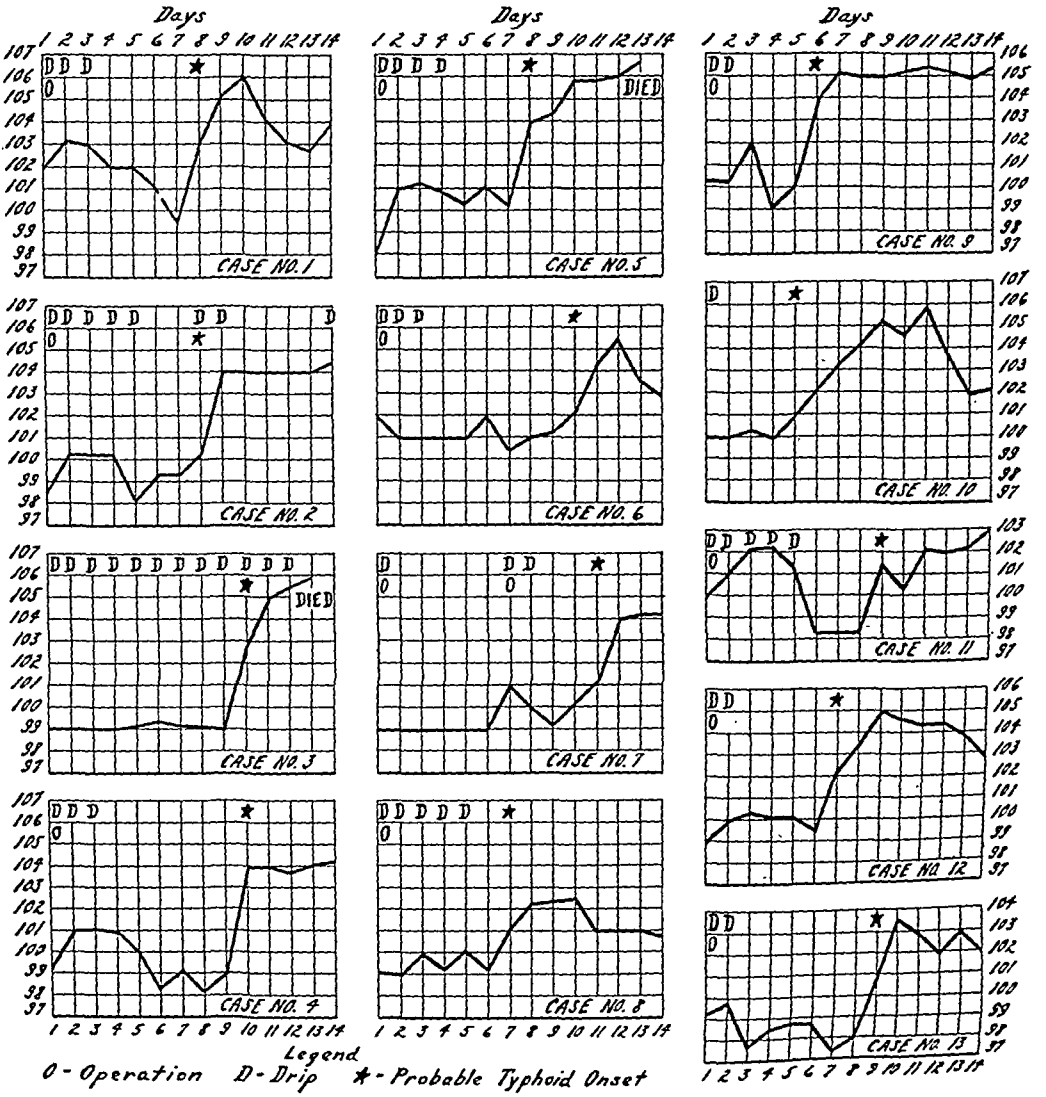
No one in the hospital developed typhoid who had not received the drip from the apparatus on the second floor.

Incubation periods were, as nearly as could be determined, as follows: 4 days in 3 cases, 6 days in 2, 7 days in 3, 8 days in 2, and 9 days in 3. The average period was between 6 and 7 days.

This is about one-half to one-third the usual incubation period in typhoid by infection by mouth, though incubation periods as short as 2 and 3 days have been ascribed to cases so infected.

Figure I shows the temperature curves from the first drip administrations to the rises indicative of the onsets. These were all major operative cases, and postoperative temperatures frequently occurred. But the rises of temperature on the dates of ascribed onset were usually so sharp, and the symptoms of the patients were so severe, that they seem quite certainly to indicate a superimposed infection. No infection of a surgical nature could be found and it seems fair to ascribe them to the typhoid fever. The onsets were usually initiated by chills, and the temperature rose almost to maximum height within the first 24 hours in the majority of cases.

Contact between cases other than by the drip medium; contact with a carrier or carriers among nurses, or other employes; infection outside the hospital, excepting in case 1; and food or water infection; seem to be satisfactorily excluded by the following considerations:



Contact between Typhoid Cases—Opportunity for contact infection might seem to have existed in the 4 rooms having 2 beds each. Two of these were occupied by male, and the other 2 by female patients. We will consider the rooms severally as numbered, 1, 2, 3, and 4.

Room 1—A medical case occupied this room with case 1 from January 10 to January 28; that is, during the incubation period, and for 4 days after the onset. He did not have the drip, and did not contract typhoid.

Case 8 also occupied this room while case 1 was in the height of his fever, from February 5 to February 9. He was administered the drip on each of these days, and developed typhoid on February 12, 7 days after the first drip. This patient was 79 years of age and was operated upon immediately after admission for ruptured appendix. The chance of infection by mouth cannot be certainly ruled out, but when the age and the diet of such a case are considered, the chance seems very remote.

Room 2—Case 4 occupied this room for 4 days after receiving the drip, but was removed therefrom on February 2, 5 days preceding her attack. Case 6 was here with case 4 only over the night of February 1. Case 6 had the drip on February 2, 3 and 4. Her attack occurred on February 12. Case 13 occupied room

FIGURE I—Excerpts from Temperature Charts of Typhoid Patients, Showing Relation of Incubation Periods to Harris Drip

2 with case 6 from February 10 to 14, 2 days before and 2 days after the onset of case 6. She had the drip on February 11 and 12. Her attack occurred 8 days after the first administration.

Room 3—A medical case occupied room 3 with case 11, during his incubation period, and for the first day of his attack. He did not have a drip and was not infected.

Room 4—A medical case occupied room 4 with case 2 during the incubation period, and for 8 days after the onset of attack. She did not have the drip, and did not contract typhoid.

Only 3 of the 13 cases occupied rooms with cases having earlier onsets. Thus, of the 6 room contacts, the 3 without drips did not contract typhoid; whereas, the 3 having the drips did. There seems little, therefore, on which to base a theory of

infection by contact other than the drip. Furthermore, 4 medical cases in an adjacent ward, and 4 in contiguous private rooms, under conditions apparently identical, but who did not have the drip, did not contract typhoid.

A Carrier among Nurses or Other Employes—A search was made for a carrier among nurses and employes who might have infected the drip containers, or the food supply. Blood, urine and fecal specimens from each nurse in the institution, and from all inside employes, were found negative. The patients affected were served by 18 special nurses, who did not interchange services between rooms.

Infection Outside the Hospital—Eight of the 13 cases came to the hospital from widely separated communities in which no known typhoid had existed for months, and in some instances for years. Five were from the city, where typhoid occasionally occurs but where no known typhoid had occurred for several weeks. There is no reason to suspect any excepting the first case of being in the incubation period on entrance. It would be absurd to postulate that each of these individuals contracted typhoid outside, and came together to develop it on the second floor of this hospital.

Food and Water—Food for the patients and employes was prepared in the general kitchen in the basement of the main building. For private room patients it was served on dishes in the central diet kitchen, taken to the various floors, and distributed by the nurses to their charges. Food for the ward patients was taken in bulk to the several ward diet kitchens where it was placed on dishes, and distributed. The same food supply served the whole institution, the only difference being in the method of distribution.

Milk used was from a pasteurized supply, from a dairy furnishing 34 per cent of the milk of the city. It was conveyed to the hospital in 25-gallon cans and served to the floors in pitchers and jugs. Water was from the city supply, which was chlorinated, filtered, and under competent supervision at all times.

The absence of typhoid at this time in the city, and among other patients in the institution, would exempt both the milk and water from suspicion.

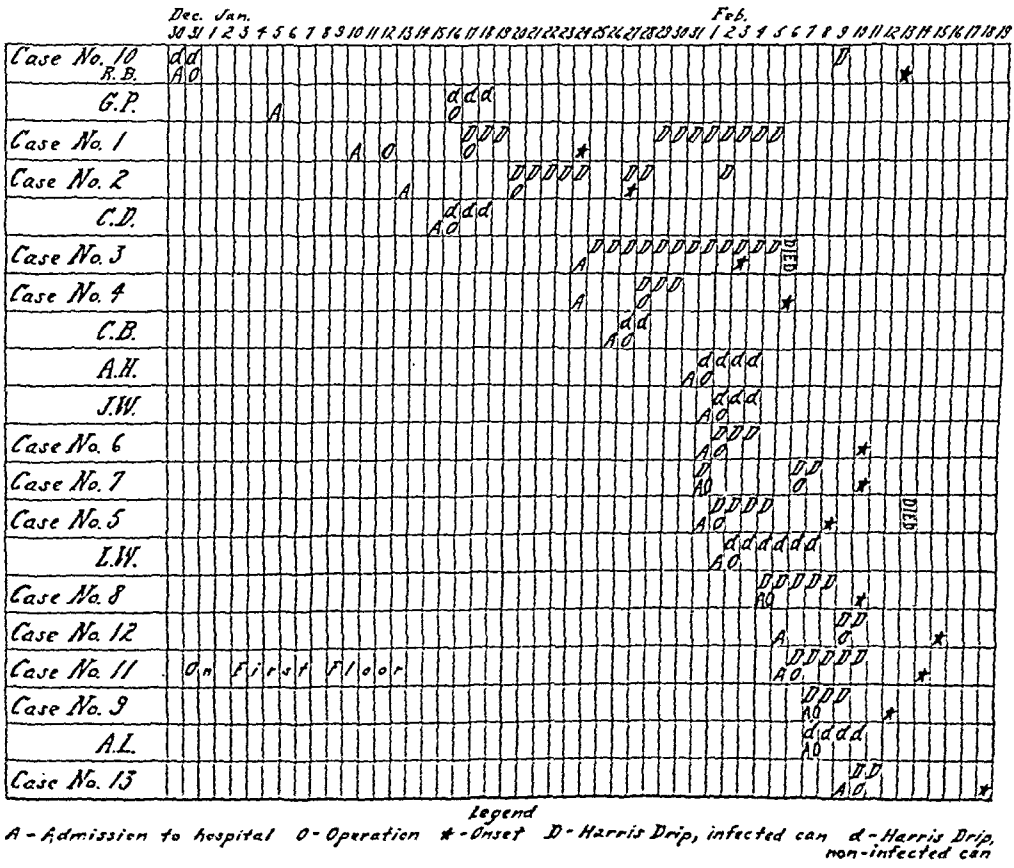
A persistent attempt was made to discover the identity of any individual, other than case 1, who might have infected the first container. In this pursuit specimens of urine, blood and feces of all patients, with one exception, on the second floor, who had received the drip within 25 days preceding the onset of the first case, were examined and found negative. The exception was a person who had left the locality without known address, but the hospital records show that this patient had not had typhoid fever.

Case 11 furnishes additional evidence against the Harris drip container. This patient was taken to a private room on the first floor after a cholecystectomy. A drip apparatus, taken from case 5, was used on February 7, 8, 9 and 10. The last use of the apparatus by case 5 was on February 5. This case was then in the 4th day of his 7-day incubation period. Nine days later the onset occurred in case 11.

The significant sequence of events determining this outbreak seems to us to be as follows: Between January 10, the date of admission of the patient first to develop typhoid, and until they were sterilized, 7 apparatuses were used on this floor in the treatment of 20 cases. It was a common procedure to retain the apparatus in a room until drips were discontinued, but as no rule existed to the contrary, they were sometimes interchanged between rooms, or taken to the floor wash-room, tubes boiled, containers rinsed, and left, unless the patient was to continue the treatment.

Figure II shows the date of admission of every patient receiving the Harris drip between December 30 and February 13. It also shows

FIGURE II—Patients in Surgical Group, Arranged according to Date of Admission



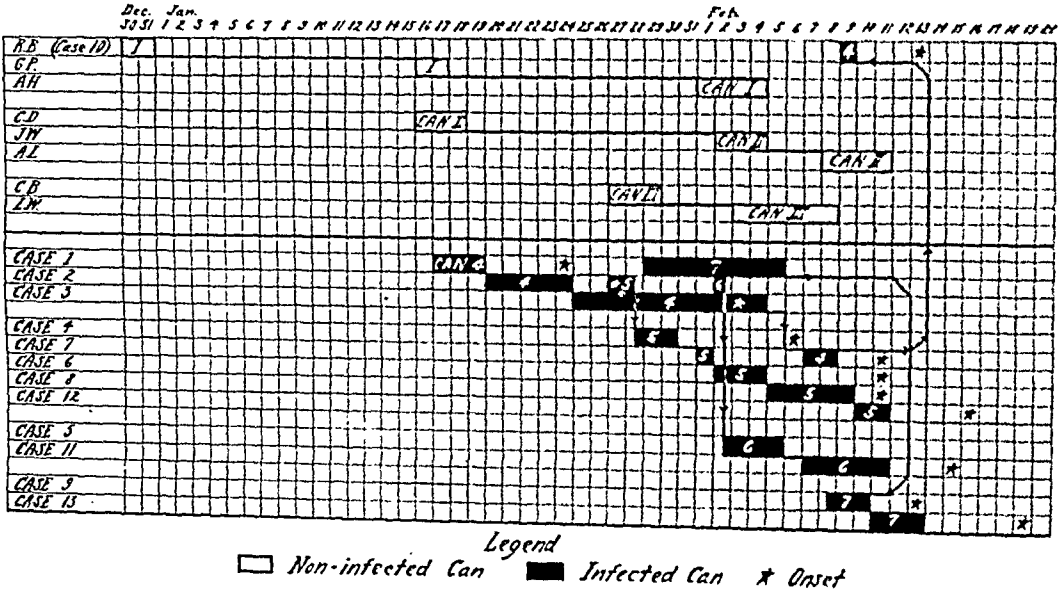


FIGURE III—Sequence of Events

the date of operation, the dates on which the drip was used and the dates of onset in those who contracted typhoid.

Drips which did not apparently result in infection are designated by a small "d," those which did, by a large "D." From this chart, we have been able to deduce a sequence of events graphically shown in Figure III, which would account for all of the infections having come from case 1, and at the same time account for the escape of the 7 unaffected individuals.

SUMMARY AND CONCLUSION

Thirteen cases of typhoid fever occurring in a hospital of 118 beds were all among a group of 20 surgical patients, to each of whom a rectal drip had been administered.

Gross pollution of drip apparatus occurred regularly when in use.

After use the containers were rinsed but not sterilized.

Other routes of infection have been excluded beyond reasonable doubt.

Case 1 developed typhoid on the 14th day after admission to the hospital and it is not unreasonable to postulate that he was infected before admission. No other sources of infection were found on laboratory examinations of the excreta and blood of other patients, attendants, etc.

In the instance of case 11, an apparatus known to have been taken directly from case 5 was used and typhoid developed 8 days later.

A hypothetical sequence in the exchange of apparatus, compatible with known facts, has been shown, which would account for the entire epidemic.

Failure of Standard Method for Visible Dirt in Milk to Meet Connecticut Requirements*

FRIEND LEE MICKLE, M. S., FELLOW A. P. H. A.

Director, Bureau of Laboratories, Connecticut State Department of Health, Hartford, Conn.

THE third, fourth and fifth editions of *Standard Methods of Milk Analysis*[1] have contained not only directions for making the test for visible dirt in milk essentially as previously described by Schroeder,[2] but have included as well the standards for grading and reporting suggested by that author. The Connecticut modification of the test, published by Mickle,[3, 4] was adopted by the approved milk laboratories of that state because the technic in *Standard Methods* was too ambiguously worded to result in uniform findings in the various laboratories. The modification has found favor with laboratory workers, but its use has demonstrated the need in Connecticut for new standards for grading all milk samples. Particularly have the present standards been shown to be unadapted for use on milk as delivered to the consumer. This has resulted because milk that would have been accepted as clean when the present standards were originally developed would today be considered dirty milk with the present methods of clarification.

The results of 6 months' experience in the use of the Connecticut modification are given in Tables I and II to call attention that, although the standards are easily used in the laboratory, the results reveal a need for changing the value of the descriptive terms used jointly in the *Standard Methods* and the Connecticut modification so that, for example, milk containing as much visible sediment as represented by 1.25 mg. per pint will no longer be classed as clean milk.

Table I summarizes the results of 6 months' testing of all samples of bottled and bulk milk received at the Bureau of Laboratories of the Connecticut State Department of Health. Out of a total of 2,331 samples tested, 2,193 (94.1 per cent) were graded as showing less

* Read at a Joint Session of the Laboratory and the Food, Drugs and Nutrition Sections of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 15, 1928.

TABLE I

RESULTS FROM 6 MONTHS' USE OF CONNECTICUT MODIFICATION OF MILK SEDIMENT TEST BY STATE DEPARTMENT OF HEALTH

Milligrams per Pint	Percentages[1]	Samples Tested	Percentages[2]	Cleanliness Ratings[2]
0.00	94.1	541	61.5	Clean and Fairly Clean
0.25		886		
0.50		505	21.5	Acceptable
0.75		157	14.5	Dirty
1.00		104		
1.25	5.9	79		
2.50		47	2.5	Very Dirty
3.75		10		
5.00		2		
Total	100	2,331	100	

1. Of all samples of bottled and bulk milk tested, 94.1 per cent fell inside limits of Connecticut standard; 5.9 per cent fell outside and were graded according to standard method.
2. The right hand two columns show approximately how samples would have been graded by author's suggested "Cleanliness Ratings," with the new values suggested by the author for the descriptive terms.

than 1.25 mg. of dirt per pt. All these were graded as "clean" under the standard method but by the procedure suggested in this paper only 23.5 per cent of the total would have been grouped as "clean" while 38.0 per cent would have fallen in the class of "fairly clean," 21.5 per cent in the class of "acceptable," and the balance would have been considered as "dirty." The latter grouping far better meets the need of the enforcement official.

In Table II is presented a summary of the results secured by the New Haven City Health Department* over a period of nearly 6 months. These examinations were all made on pint samples. The director of that laboratory has informed the writer that he has found the method in the fifth edition of *Standard Methods* "cannot be applied to the general run of samples of New Haven milk unless every sample is called clean, but that the method as modified by the Milk Laboratory Workers Association of Connecticut and adopted by that organization for all Connecticut approved laboratories, at a meeting

* Results obtained in the Bureau of Laboratories of the New Haven Health Department were furnished by P. E. Bransfield, Director. They have been arranged in tabular form to make them conform with Table I and to illustrate how they would have been graded by the author's suggested classification.

TABLE II

RESULTS FROM NEARLY 6 MONTHS' USE OF CONNECTICUT MODIFICATION OF MILK SEDIMENT TEST BY NEW HAVEN DEPARTMENT OF HEALTH

Milligrams per Pint	Percentages[1]	Samples Tested	Percentages[2]	Cleanliness Ratings[2]
0.00	99.8	526	97.2	Clean and Fairly Clean
0.25		96		
0.50		12	1.8	Acceptable
0.75		5	0.8	Dirty
1.00

3.75		1*		
5.00				
Total	100	640	100	

1. All the samples included in this table were pint samples of bottled milk. Of these, 99.8 per cent fell within limits of Connecticut standard; 0.2 per cent fell outside and were graded according to standard method.
2. The right hand two columns show approximately how samples would have been graded by author's suggested "Cleanliness Ratings," with the new values suggested by the author for the descriptive terms.
* "The indications are that the dirt in this sample of milk came from a dirty bottle, which for some reason escaped being washed, rather than that the dirt was in the milk itself. In my opinion, this one sample should be considered an accident."—Excerpt from letter from P. E. Bransfield, who furnished these data.

held in Hartford on January 9, 1928, is quite satisfactory for milk sold in New Haven," and adds that from the results obtained "it would seem that the A. P. H. A. Standards could be applied only to can or bulk milk in New Haven."

Connecticut officials charged with enforcing regulatory measures have been outspoken against the laboratories, following the standard method, having to class as "clean," milk that in this section of the country is considered dirty. Much of the value of the test as used in Connecticut has been educational in the way of elimination of sediment from milk as sold, by repeatedly impressing on the producer the desirability of marketing a milk a little cleaner than his competitor's. Granted that many times a "cleaned," rather than a "clean" milk undoubtedly reaches the housewife, the use of the test has surely been a factor, coupled with intelligent inspection and modern competition, in enormously reducing the visible dirt in market milk. To grade as "clean" samples showing 1.00, or as "fairly clean" samples showing 1.25 mg. of sediment per pt., if from milk as offered in trade today, would seem to be inconsistent with modern health education and

propaganda. For the purposes of the enforcement official it does not remedy the matter greatly to state on the report: "Where bottled milk is examined it should not show even 1.25 mg. of sediment per pt." if the sample is graded as "clean" or "fairly clean." Connecticut milk can scarcely be so much cleaner than that in other states that similar conditions do not prevail elsewhere. The undesirability of one state adopting a standard at variance with that in use elsewhere is evident in view of the frequency of milk surveys comparing results secured over broad areas.

As a result of his experience with the test, the author suggests the following changes in the standard method, and in the Connecticut modification as well, wholly in a spirit of constructive criticism with full realization that the committees on standard methods have never recommended the test for grading market milk samples at city and state laboratories in milk control work. On the other hand, it is believed the test should be as extensively used for that purpose as for grading milk at milk receiving stations and, accordingly, that it should be modified to more satisfactorily meet that need although it should not fail to meet as well the requirements for the rapid testing necessary at the receiving plant.

SUGGESTED CHANGES

1. *Size of Sample*—Pint samples should be continued as standard. Where larger samples either of bottled or bulk milk are received they should be thoroughly mixed and only 1 pint filtered. Where less than 1 pint of sample is examined the disc obtained should be graded directly against the photographic standard described below and the numerical result proportioned to a pint basis and then, but not until then, the accompanying descriptive term applied. This is desirable because, otherwise, if samples of various sizes are reported on one report, the results may be misleading. The size of sample should always be stated on the report when it is less than a pint. To state the size without making the calculation does not suffice because the result is expressed on the basis of the number of milligrams in a pint.

2. *Specifications for Testing Equipment*—It is rather desirable that the same type of tester be used in different laboratories, particularly as the discs furnished with the different testers may vary decidedly in thickness, texture and density. Specifications for a satisfactory testing device and for the cotton pads might well be incorporated in the method.

3. *Photographic Standard*—In Connecticut experience there has been far greater disagreement when individual laboratories attempted to prepare standard gauges by adding dirt to milk according to published directions than when a central agency prepared such a standard, photographed it, and distributed photographs to the laboratories to use as standards in grading the sediment obtained from filtering milk samples. It is very necessary that care be taken in eliminating shadows when making the negative of the photographic standard if prints are to be uniform. The prints distributed to laboratories to use as standards should be printed in large

numbers at a time on a photographic paper found by trial to be adapted to the purpose, and the light used and length of exposure should be such that conditions can be closely reproduced later. Several photographs purposely printed for different lengths of time were found to give comparable results in grading, however, when the precaution had been taken to eliminate shadows in making the original negative.

Grading should in no case be done against a reproduction from a printer's cut such as has been reproduced in *Standard Methods*. It is customary and almost a necessity in some laboratories where a large amount of grading is done to protect the photographic standard by framing it under glass. The author has not been able to see any objection to one laboratory using a framed and another an unframed photograph but the desirability of this practice might be considered.

The use of carbon of suitable density and proper size of particles, as has been suggested by Harding[6] (1928) and others, may be an improvement later but is not considered necessary for a usable photographic standard. It is understood that a committee of the International Association of Dairy and Milk Inspectors is investigating the possibilities of different grades of carbon as this is written. The suggestion has recently been made to the author that other substances, for example, manganese dioxide (pyrolusite), might be even better adapted to the purpose and it is hoped this material can be given a trial in the near future.

In preparing the standard discs for photographing, a "standard" dirt should be secured in quantity by the committee. A mixture of stable dirt from several sources has proved satisfactory for the purpose providing its density is increased slightly, if necessary, by the addition of a small amount of finely ground sand or similar material before the weighings are made. The stable dirt most comparable with that obtained from market milk in Connecticut was that which passed a 100-mesh sieve. The size of the sand particles should be slightly smaller than that of the dirt particles to render them unnoticeable.

4. *Discs Not to be Kept on File*—The entire disc should preferably in all cases be returned to the dairyman, health or dairy official or milk inspector with the report, and preferably attached to it. The record of the "sediment score" and "cleanliness rating" kept at the laboratory should be sufficient for record purposes in any case. In some instances it is difficult to cut discs into two portions showing equal amounts of dirt.

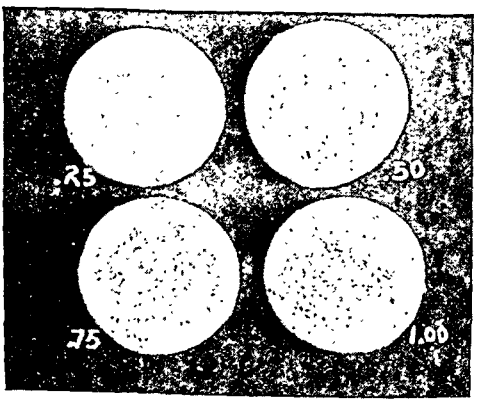

FIGURE I—CONNECTICUT SEDIMENT STANDARDS ADOPTED AT CONFERENCE OF CONNECTICUT APPROVED LABORATORY WORKERS ON JANUARY 9, 1928.

5. *Grading Large Sediment Particles*—No attempt should be made to grade as sediment any hair, piece of hay or straw or large particle of dirt. The finer dirt on the disc should be compared with the standard and reported as usual and then the report should state that sediment disc showed this material in addition.

6. *Additional Standard Gauges*—A large proportion of the specimens of milk examined in laboratories maintained by the cities and the state in Connecticut for control purposes are samples of bottled milk just as sold to consumers or of milk sampled from cans as delivered to schools, institutions or eating places. Figures given below demonstrate that very few of

these show as much sediment as that on the disc representing 1.00 mg. per pt. Since that is true, additional standards (Figure I) are recommended for use on milk as sold to the consumer, representing, respectively, 0.25, 0.50, 0.75 and 1.00 mg. per pt. Otherwise nearly all the samples examined will be placed in the one grade of "clean" and the work of making the test nullified. That these amounts have proved suitable for the purpose is shown in Tables I and II and in the discussion of the tabulated results.

7. *Descriptive Terms in Standard Methods Should be Changed*—The gauges pictured in the fifth edition of *Standard Methods* appear to be very usable at the farm and the receiving plant but the descriptive terms are not very apt for use on bottled milk and should be changed. Attention is called to the undesirability of having two sets of standards if that can be avoided, for many times on one report there may be tabulated a set of samples with some representing bottled or market milk and others representing samples collected at the farm or the milk plant. The author sees that occur almost daily. It would appear to be so unfortunate to have to mark one sediment disc attached to the report as "slightly dirty" and a dirtier one "clean," because two differing standards were being used, that the writer suggests the same gradings for all milk samples. It would seem desirable that standards be continued as a part of the printed method to discourage the upgrowth of a variety of standards in other ways and through other organizations.

8. *Terms for Reporting*—The term "milligrams per pint" is not strictly accurate since only a visual comparison of the obtained sediment is made with another "standard" sediment without taking into account the differences in density. That is the case whether or not the actual gauges or photographic standards are used for grading. Furthermore the term is cumbersome and not easily understood by many enforcement officials and dairymen. It is suggested the term "milligrams per pint" be abandoned in favor of an arbitrary standard in which the milligrams or fraction of a milligram of dirt in each instance would be multiplied by 100 to give for the eight standard gauges the corresponding eight whole numbers: 0, 25, 50, 75, 100, 125, 250 and 500, to be known as a "sediment score." Milk samples would then be graded as in Table III.

TABLE III

CHART FOR GRADING VISIBLE SEDIMENT IN MILK ACCORDING TO AUTHOR'S SUGGESTED METHOD

Terms Not to be Reported	Terms to be Reported	
Milligrams per Pint	Sediment Score	Cleanliness Ratings
.00–0.12	0	Clean
.13–0.37	25	Fairly Clean
.38–0.62	50	Acceptable
.63–0.87	75	Slightly Dirty
.88–1.12	100	Dirty
1.13–1.77	125	Very Dirty
1.78–3.75	250	Very Dirty
3.76–5.00+	500	Very Dirty

It is suggested that no "sediment score" be reported within closer limits than the eight units listed.

Results of any milk sediment test for visible dirt should always be reported both in terms of the "sediment score" and also by one of the descriptive terms for

"*cleanliness rating.*" It is possible that other descriptive terms than "clean" and "dirty" may be found preferable to those terms.

SUMMARY

The standard method for visible dirt in milk and the modification adopted for Connecticut approved health laboratories and recently published by the author are discussed. Results justify the modification for Connecticut market milk but suggest new terms for reporting. A universally adopted photographic standard distributed by the Committee on Standard Methods is urged in place of standards made by individual laboratories. Because the method aims at determining amount and not color of dirt a photographic standard should be applicable in any locality regardless of color of local soil. Connecticut experience demonstrates that satisfactory photographic standards can be prepared from discs with weighed amounts of stable dirt of proper specific gravity if shadows are eliminated in photographing. A standard carbon in place of stable dirt is not necessary, although its adoption later might improve the photographic standards. The term "milligrams per pint" is not readily understandable and is inaccurate; so photographic discs should be assigned arbitrary numerical values to be reported always together with corresponding descriptive terms.

Women and Children in Industry

THE medical inspectors of factories in the duchy of Baden, Germany, have completed an investigation in an industrial and a rural district to determine the effect of factory and of farm work on the health of women workers and of children. Most of the industrial workers were employed in textile factories. In the course of the study the investigators interviewed women workers and their employers.

In both the industrial and the rural regions the average mortality rate for 1920–1926 for women of wage earning ages was higher than the rate for men of the same ages, apparently on account of the excessive fatigue caused by the double duty of wage earning and housekeeping. The factory work itself did not seem to have a bad effect on the health of the women workers.—*Reichsarbeitsblatt*, Berlin, Nos. 17 and 20, 1928.

Effect of Calmette's BCG Vaccine on Experimental Animals*

MERRILL J. KING, M. D., AND WILLIAM H. PARK, M. D.,
FELLOW A. P. H. A.

Hegeman Memorial Research Laboratory, Metropolitan Life Insurance Company Sanatorium, Mount McGregor, N. Y.; and the Bureau of Laboratories, Department of Health, New York, N. Y.

MANY methods of prophylactic immunization against tuberculosis have been recommended and attempted by such men as Koch, Pasteur, Baldwin, Theobald Smith, Trudeau, Pearson and Gilliland, Von Behring and others. During the past few years considerable publicity has been given the BCG vaccine of Calmette and some difference of opinion has been reflected in the literature regarding the efficacy of this vaccine, and especially regarding the danger that may be connected with its use in infants.

The *Bacillus Calmette-Guérin,* which is the so-called BCG, was isolated from a heifer in 1908 by Calmette and his associates. They determined it to be the bovine type of tubercle bacillus and to possess moderate virulence for guinea pigs, rabbits and cattle. Continuous cultivation over a period of years on glycerinated ox-bile potato medium reduced the virulence of the organism so that it will now produce only small localized tubercles which heal within a few months. They further state that it is able to produce skin hypersensitiveness and immunity against infection with virulent tubercle bacilli.

Calmette first recommended that new-born infants be fed the BCG, and it was so administered in 1921 at the Maternity Hospital in Paris. Since that time nearly 100,000 infants have been given this prophylactic vaccination, but only a relatively small number of these have been recorded in statistical studies, and the reports of Calmette have been attacked as being statistically incorrect. Calmette is convinced of the innocuousness of the vaccine and of its ability to immunize against tuberculosis, and many workers have found the bacillus to be non-virulent for small laboratory animals. Others have been able to

* Read before the Laboratory Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

produce progressive disease, and Nobel[1] and Gerlach[2] were able to carry the lesion successively from guinea pig to guinea pig. Petroff and Branch[3] have produced progressive tuberculosis and death in guinea pigs and have dissociated the original Calmette culture into two strains—the "R" type which always produces some tubercles which in time heal, and the "S" type which invariably produces progressive disease terminating in death, in the guinea pig.

The BCG culture used in these studies was obtained directly from Dr. Calmette. The organism has been continuously cultivated on ox-bile glycerinated potato medium and we have endeavored to follow Calmette's instructions implicitly in this regard. We have found no difficulty in getting profuse growths. The colonies, which usually appear in about two weeks, are clear-cut and moist, but they soon dry and pile up rapidly and culturally resemble Petroff's "R" type, and in being difficult to emulsify have further agreed with his description. All animals which have died or been killed have had postmortem examinations and, in the majority of cases, reinoculations have been made. We have deliberately kept the groups of vaccinated animals small in order that we might test as many different transplants of the culture as possible. In these preliminary experiments the primary interest was in assuring ourselves of the innocuousness of the BCG for guinea pigs, monkeys and calves. The experiments are being continued and will be reported in more detail at a later time.

The experiments have been arranged in three main groups, according to the method of administration of the BCG: (1) oral, (2) subcutaneous and (3) intraperitoneal.

VACCINATION BY MOUTH

Guinea Pigs—Three groups of week-old guinea pigs were fed the vaccine as follows:

Guinea Pigs	50 mg. each		
6	3 feedings	Killed 25 weeks	Negative
6	3 feedings	Killed 21 weeks	Negative
12	7 feedings	Killed 27 weeks	Negative

Calves—Seven new-born calves were fed with the following results:

Calves	50 mg. each		
5	5 feedings	Killed 51 weeks	Negative
1	5 feedings	Killed 5 weeks	Negative
1	5 feedings	Living 2½ years	Negative tuberculin

Monkeys—Ten monkeys receiving from 3 to 12 feedings each, gave more interesting results (see top of next page).

The 4 monkeys which had tuberculous lesions had only small, discrete non-caseous tubercles of the lymph nodes. Two monkeys also had similar lesions in the spleen. Although infrequent acid-fast rods were present in the tubercles of 3 of

Monkeys	50 mg. each			
2	3 feedings	Killed	8 weeks	Negative
1	6 feedings	Died	8 weeks	Negative
1	9 feedings	Died	8 weeks	Negative
1	11 feedings	Killed	8 weeks	Negative
1	6 feedings	Died	13 months	Tubercles spleen, mesenteric nodes
1	11 feedings	Killed	8 weeks	Tubercles of mesenteric nodes, spleen
1	12 feedings	Killed	13 months	Tubercles of mesenteric nodes
1	12 feedings	Killed	23 months	Tubercles of mesenteric nodes
1	6 feedings	Living	$2\frac{1}{2}$ years	

these, triturates of the viscera and nodes failed to produce lesions when injected into normal guinea pigs.

The results of the feeding experiments show that we were unable to find evidence of the absorption of the BCG in 24 guinea pigs and 7 calves, whereas 4 of the 9 monkeys had small discrete tubercles in their mesenteric nodes.

ORAL VACCINATION FOLLOWED BY INFECTION WITH VIRULENT BACILLI

Guinea Pigs—Three groups of week-old guinea pigs are listed below. These animals were given 3 to 7 feedings of 50 mg. each.

Guinea Pigs	Interval	Infecting Dose	Method			Result
3	9 weeks	0.02 mg. bovine	Subcut.	Killed	21 weeks	Generalized tuberculosis
4	13 weeks	0.10 mg. bovine	Subcut.	Killed	13 weeks	Generalized tuberculosis
12	13 weeks	0.10 mg. human	Subcut.	Killed	8 weeks	Generalized tuberculosis

Eleven non-vaccinated controls gave the same tuberculous picture as the vaccinated animals.

Calves—Eight new-born calves, each receiving 5 feedings of 50 mg. each, and 7 non-vaccinated controls were included in this series.

Calves	Interval	Infecting Dose	Method			Result
2	30 weeks	10.0 mg. bovine	Subcut.	Killed	10 weeks	Localized cold abscess
				Control	10 weeks	Localized cold abscess
1	16 weeks	5.0 mg. bovine	Subcut.	Killed	36 weeks	Negative
				Control	10 weeks	Localized cold abscess
1	16 weeks	5.0 mg. bovine	Subcut.	Killed	36 weeks	Tuberculous node
				Control	10 weeks	Localized cold abscess
1	16 weeks	5.0 mg. bovine	Subcut.	Killed	10 weeks	Localized cold abscess
				Control	10 weeks	Localized cold abscess
1	30 weeks	1.0 mg. bovine	Vein	Killed	10 weeks	Bronchial, mediastinal nodes
				Control	10 weeks	Bronchial, mediastinal nodes
1	30 weeks	0.1 mg. bovine	Vein	Killed	10 weeks	Negative
				Control	10 weeks	Bronchial, mediastinal nodes
1	22 weeks	20.0 mg. bovine	Fed 2X	Killed	20 weeks	Negative
				Control	21 weeks	Negative

Two animals in this series failed to develop tuberculous lesions while their corresponding controls became infected. The attempt to infect by feeding was unsuccessful, neither control nor vaccinated calf reacting after two doses of 10 mg. each of bovine bacilli.

Monkey—One monkey was given 4 feedings of 50 mg. each, and 16 weeks after the last feeding it was injected subcutaneously with 0.3 c.c. of a very dilute suspension of human tubercle bacilli, and when killed 56 days later because of an open sinus at the site of inoculation it had, in addition to the local abscess, about

a dozen pea-sized caseous tubercles in the liver and spleen. Two control monkeys receiving the same dose of virulent organisms died on the 57th and 62d days respectively with massive tuberculosis of the viscera.

SUBCUTANEOUS VACCINATION

Guinea Pigs—Four groups totalling 22 guinea pigs were inoculated subcutaneously as follows:

Guinea Pigs			Result
1	3 mg.	Killed 13 months	Negative
1	3 mg.	Killed 18 months	Histological tubercles in lymph nodes, infrequent acid-fast rods
1	5 mg.	Killed 3 months	Histological tubercles in lymph nodes, infrequent acid-fast rods
1	5 mg.	Killed 3 months	Histological tubercles in lymph nodes, infrequent acid-fast rods
1	25 mg.	Killed 10 months	Negative
1	50 mg.	Killed 14 months	Negative
1	50 mg.	Living 14 months	
2	25 mg.	Living 14 months	
1	25 mg.	Killed 1 month	Histological tubercles in lymph nodes, acid-fast rods
1	25 mg.	Died 9 months	Secondary infection; histological tubercles, acid-fast rods
1	25 mg.	Died 9 months	Secondary infection; histological tubercles spleen
9	25 mg.	Living 15 weeks	
1	25 mg.	Died 10 weeks	Secondary infection; tubercles nodes, spleen, liver

The guinea pig in the 4th group which died of secondary infection showed an extensive tuberculosis of the mesenteric nodes, spleen and liver. The inguinal node at the site of inoculation was caseous. Acid-fast bacilli were present in the pus and in the tubercles of the mesenteric nodes and liver. This guinea pig is the only animal in our experience which has developed an extensive progressive tuberculosis after vaccination alone. The other animals in the group seem normal. One may consider that the single guinea pig which developed progressive tuberculosis is an instance of individual susceptibility. It does not seem likely that there were sufficient "S" type colonies in the small portion of vaccine inoculated to cause progressive tuberculosis in one guinea pig while the other guinea pigs in the same group have shown no evidence of progressive tuberculosis.

Two guinea pigs injected with the material from the caseous node and spleen of the tuberculous animal described above were negative to tuberculin 30 days later. One of these, killed at 32 days, showed no evidence of tuberculosis. The other is apparently normal, has gained in weight, and gives a negative tuberculin 90 days after the inoculation.

Monkeys—Eight monkeys were injected with 50 mg. each of vaccine:

Monkeys			Result
1	50 mg.	Died 37 weeks	Several pinpoint tubercles in spleen; acid-fast rods
1	50 mg.	Died 35 weeks	One macroscopic and several histological tubercles in lung and spleen; acid-fast rods
1	50 mg.	Killed 93 weeks	Negative
1	50 mg.	Killed 58 weeks	Histological tubercle in lung; acid-fast rods
4	50 mg.	Living 60 weeks	

Here again guinea pigs were injected with triturates of the nodes and spleens of the autopsied monkeys and failed to become infected.

Calves—Four groups, making a total of 46 calves, were injected, 50 mg. in each animal. Twenty-nine of these are living 9 months; 11, 5 months; and 5, 3 months after vaccinations. The 46th animal, a bull calf, gave a positive tuberculin 10 weeks after injection of the BCG, but the reaction became doubtful in the 42d week and was negative at 72 and again at 90 weeks. After the second negative tuberculin, the bull was placed on a farm to be used for breeding. The tuberculin test was repeated on the 120th week and it was found that the bull and several cows in the herd had developed positive tuberculins. The bull was slaughtered in the 124th week and was found to have tubercles in the bronchial and mediastinal nodes and in the lungs. It seems probable that this is a case of re-infection rather than evidence of the acquisition of virulence by the BCG on long residence in the animal. Calmette advises annual re-vaccination, which was not done in the case of this bull. Unfortunately it was impossible for us to be present at the autopsy; nor could we obtain the viscera in order that we might culture the bacilli in the lesions and ascertain if they were virulent.

In summarizing the subcutaneous series it should be pointed out that we were able to produce tubercles at the site of injection of the BCG in many of our animals. These lesions caseated in several instances. The production of minute tubercles in the adjacent lymph nodes occurred in the majority of the animals inoculated. Spleen involvement occurred in 4 animals with a further extension to the liver in one of these. In another animal, small tubercles were produced in the lung. One guinea pig which died 10 weeks after injection had extensive progressive tuberculosis apparently due to the BCG. Saline emulsions of the caseous material and tubercles of this guinea pig contained many acid-fast rods but failed to infect two normal guinea pigs on subinoculation. In fact, in no instance did saline emulsions and triturates of the BCG lesions of vaccinated animals produce tubercles when subinoculated into normal animals, although all of the material so inoculated contained acid-fast rods. Forty-five of the 46 calves are still living. We believe that at least 34 of these developed tubercles, since they became allergic within 12 weeks after vaccination, and 27 of 29 had lost this skin-hypersensitiveness by the 32d week.

SUBCUTANEOUS VACCINATION FOLLOWED BY INFECTION WITH VIRULENT BACILLI

Guinea Pigs—Three groups of vaccinated guinea pigs were subsequently infected by the subcutaneous method with the following results:

Guinea Pigs	BCG	Interval	Infecting Dose			Result
1	6 mg.	20 weeks	0.02 mg. bovine	Killed	2¼ years	Negative
1	6 mg.	20 weeks	0.10 mg. bovine	Killed	39 weeks	Negative
3	Controls		0.02 mg. bovine	Killed	21 weeks	Generalized tuberculosis
3	Controls		0.10 mg. bovine	Killed	52 weeks	Generalized tuberculosis
1	Control		0.10 mg. bovine	Died	52 weeks	Generalized tuberculosis

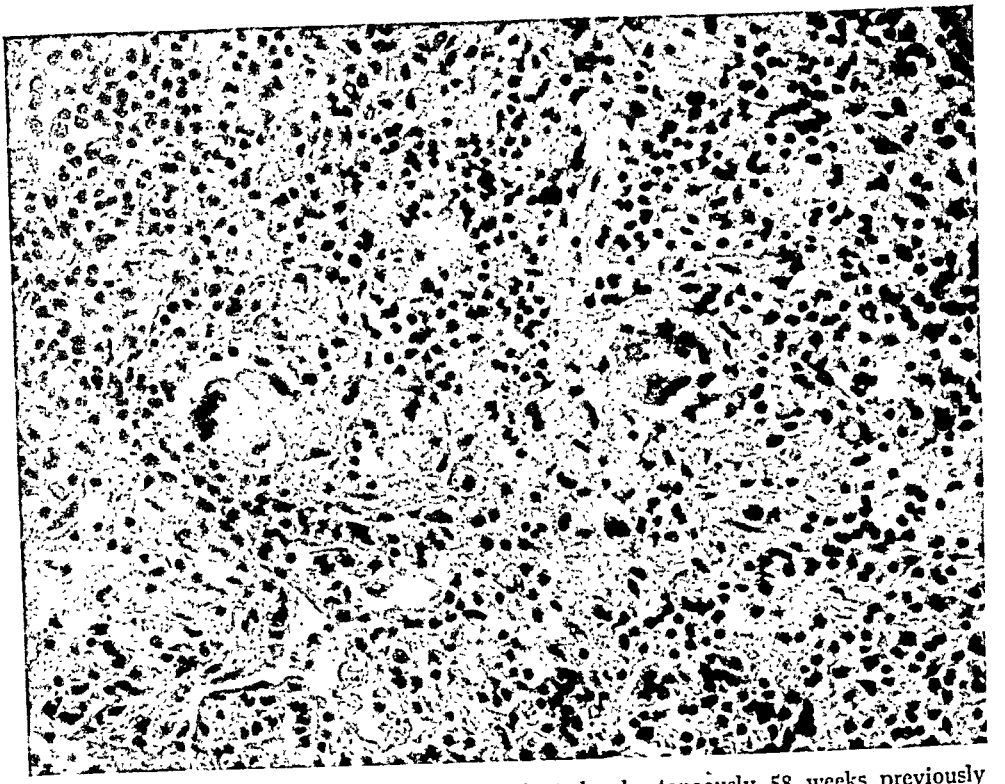

FIGURE I—Tubercle in lung of monkey vaccinated subcutaneously 58 weeks previously with 50 mg. of BCG. × 410.

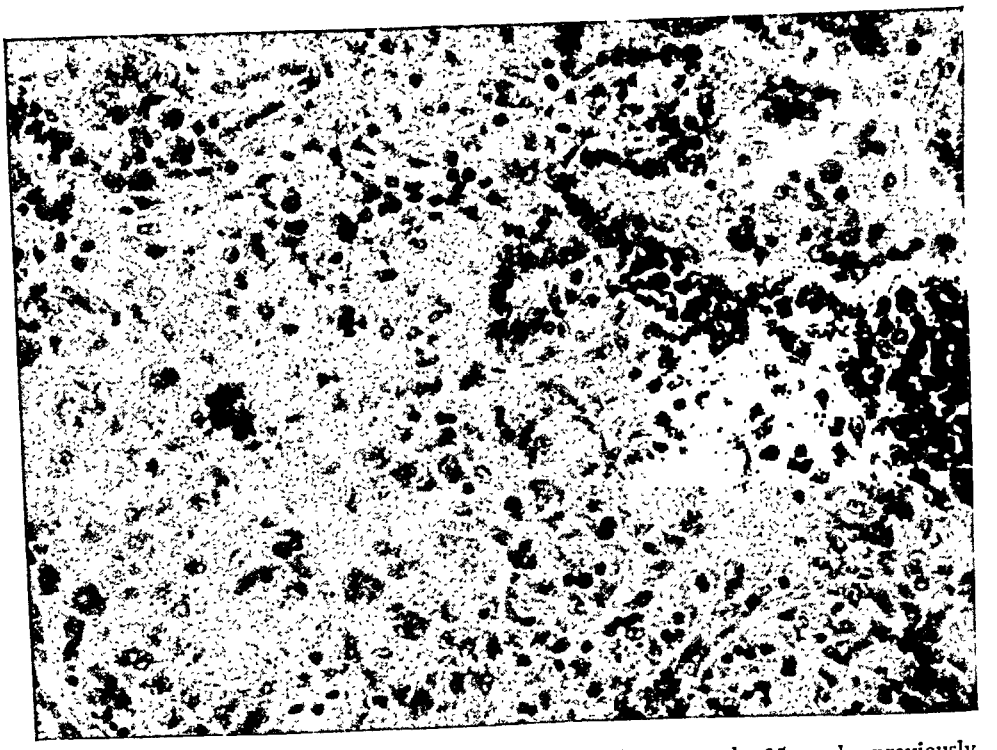

FIGURE II—Tubercle in lung of monkey vaccinated subcutaneously 35 weeks previously with 50 mg. of BCG. × 410.

FIGURE III—Caseous material from inguinal lymph node of guinea pig injected 10 weeks previously with 25 mg. of BCG into the groin. On subinoculation this material failed to infect normal guinea pigs. Ziehl-Neelson stain. × 1,810.

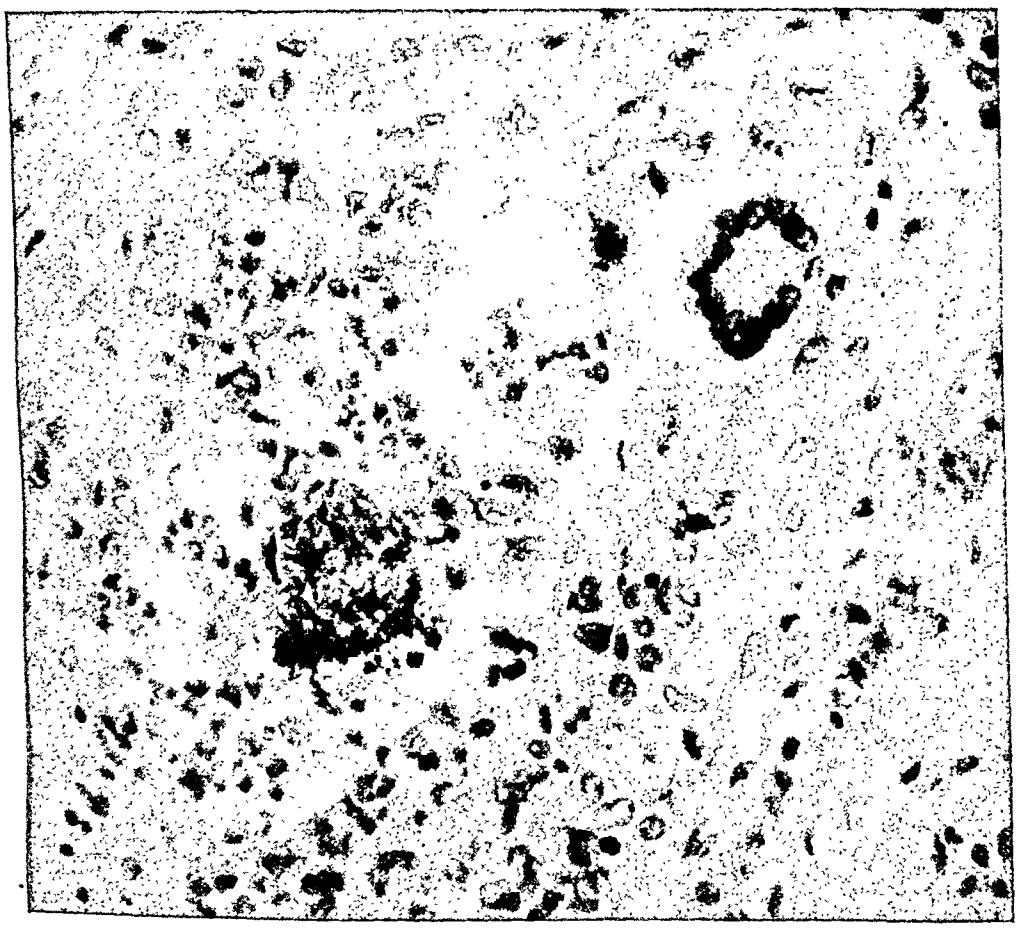

FIGURE IV—Lymph node of guinea pig vaccinated subcutaneously 10 weeks previously with 25 mg. of BCG. Ziehl-Neelson stain. × 640. Acid-fast rods were demonstrated in all lesions illustrated.

Guinea Pigs	BCG	Interval	Infecting Dose			Result
1	25 mg.	43 weeks	0.02 mg. bovine	Killed	8 months	Few discrete tubercles spleen, liver, lungs
1	25 mg.	43 weeks	0.02 mg. bovine	Killed	8 months	Few discrete tubercles spleen, liver, lungs
1	Control		0.02 mg. bovine	Died	7 months	Massive tuberculosis
2	Controls		0.02 mg. bovine	Killed	8 months	Massive tuberculosis
1	Control		0.02 mg. bovine	Died	9 months	Massive tuberculosis
1	50 mg.	4 months	0.3 c.c. human	Killed	33 weeks	Tubercles nodes, spleen
1	50 mg.	4 months	0.3 c.c. human	Died	45 weeks	Tubercles nodes, spleen
1	50 mg.	4 months	0.4 c.c. human	Killed	8 weeks	Tubercles nodes, spleen
1	25 mg.	4 months	0.5 c.c. human	Killed	23 weeks	Tubercles nodes, spleen, liver, lung
3	Controls		0.3 c.c. human	Died Av.	18 weeks	Generalized tuberculosis

There seems to be some evidence of protection in the vaccinated guinea pigs, for 2 failed to develop tuberculosis, while their controls developed extensive generalized tuberculosis. The remaining 6 guinea pigs developed tuberculosis, but much less extensively than their non-vaccinated controls.

Monkeys—Only 2 monkeys and 2 controls infected by the subcutaneous method are included in this series:

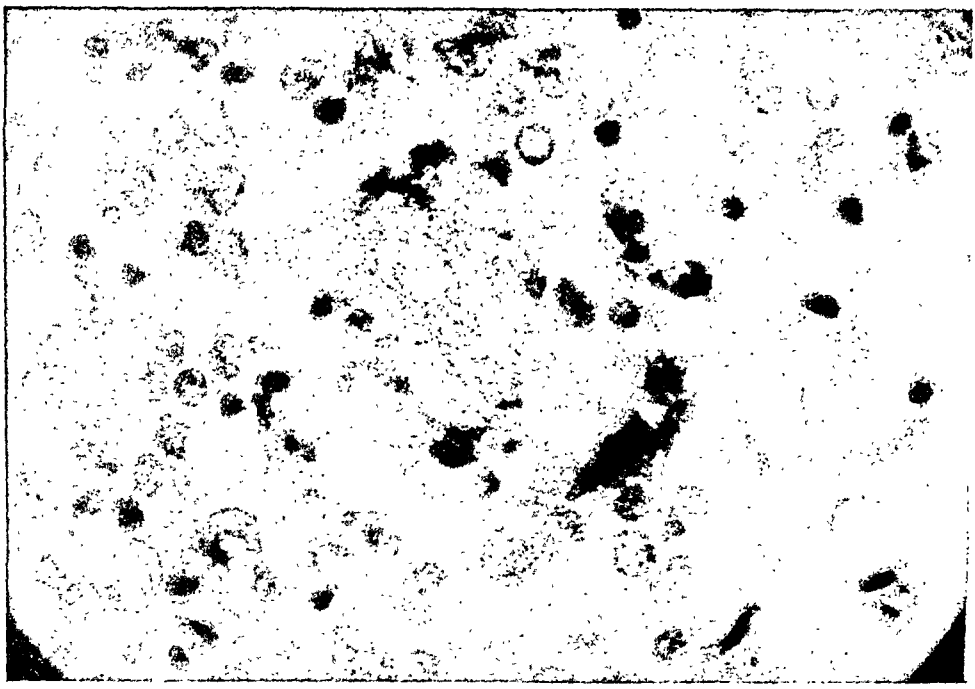
Monkeys	BCG	Interval	Infecting Dose			Result
1	50 mg.	16 weeks	0.3 c.c. human	Killed	57 days	Caseous nodes, tubercles in viscera
1	50 mg.	16 weeks	0.5 c.c. human	Killed	117 days	Caseous nodes, tubercles in viscera
1	Control		0.3 c.c. human	Died	57 days	Generalized tuberculosis
1	Control		0.5 c.c. human	Died	62 days	Generalized tuberculosis

The 2 vaccinated monkeys likewise developed more localized infection than their controls, which died in a shorter time.

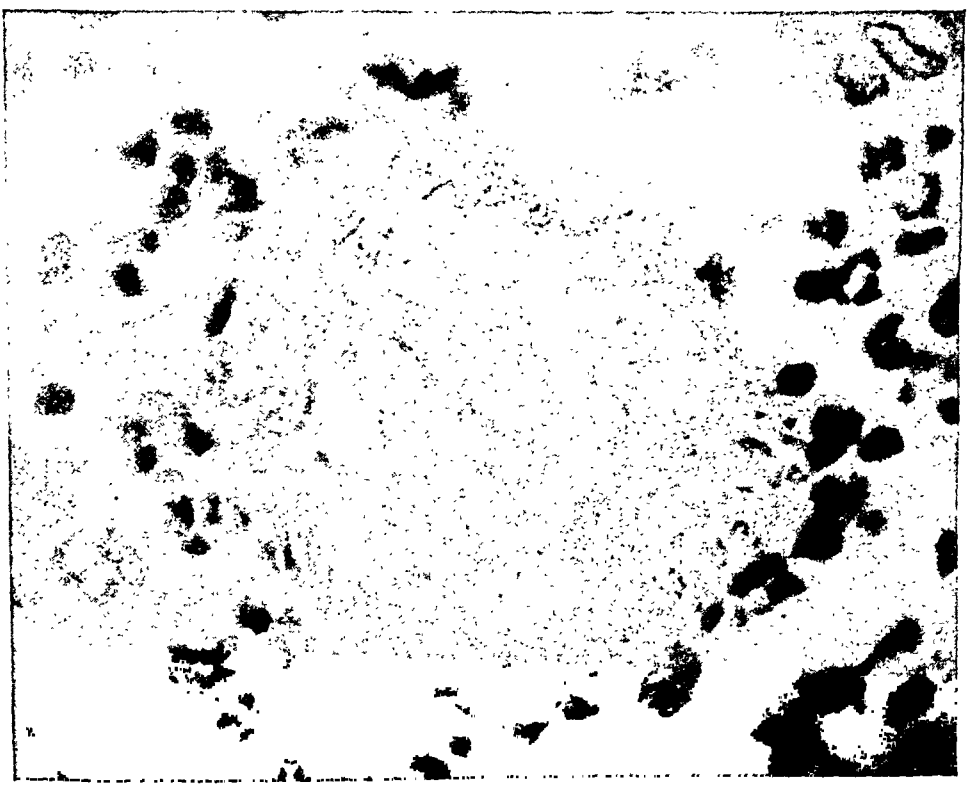
Calves—The immunity experiments in calves are composed of 16 animals which are subdivided into 5 groups.

Calves	BCG	Interval in Weeks	Dose Bovine	Method	Killed in Weeks	Result
1	50 mg.	16	5.0 mg.	Subcut.	11	Cold abscess
1	50 mg.	16	5.0 mg.	Subcut.	40	Negative
1	50 mg.	16	5.0 mg.	Subcut.	40	Few tubercles adjacent lymph node
1	Control		5.0 mg.	Subcut.	11	Cold abscess
1	Control		5.0 mg.	Subcut.	13	Tubercles adjacent node
1	Control		2.0 mg.	Subcut.	13	Tubercles adjacent node
1	50 mg.	31	10.0 mg.	Subcut.	11	Cold abscess
1	50 mg.	31	10.0 mg.	Subcut.	11	Cold abscess
1	Control		10.0 mg.	Subcut.	11	Extensive tuberculous nodes
1	50 mg.	31	1.0 mg.	Vein	11	Tubercles bronchial, mediastinal nodes
1	50 mg.	31	0.1 mg.	Vein	11	Negative
1	75 mg.	8	1.0 mg.	Vein	21	Tubercles bronchial, mediastinal nodes
1	75 mg.	8	0.1 mg.	Vein	21	Negative
1	Control		0.01 mg.	Vein	12	Tubercles broncho-mediastinal, mesenteric nodes
2	Controls		0.1 mg.	Vein	12	Tubercles broncho-mediastinal, mesenteric nodes
2	Controls		1.0 mg.	Vein	12	Tubercles broncho-mediastinal, mesenteric nodes

Calves	BCG	Interval in Weeks	Dose Bovine	Method	Killed in Weeks	Result
1	50 mg.	22	0.01 mg.	Subcut.	44	Negative
1	50 mg.	22	0.01 mg.	Subcut.	44	Negative
1	50 mg.	66	0.01 mg.	Subcut.	22	Negative
1	50 mg.	66	0.10 mg.	Subcut.	22	Negative
1	Control		0.05 mg.	Subcut.	12	Negative
1	Control		0.02 mg.	Subcut.	25	Negative
1	Control		0.01 mg.	Subcut.	34	Negative
1	Control		0.10 mg.	Subcut.	34	Negative
1	50 mg.	21	100 mg.	Fed 2X	20	Negative
1	50 mg.	21	250 mg.	Fed 5X	20	Negative
1	50 mg.	21	500 mg.	Fed 5X	20	Negative
2	Controls		300 mg.	Fed 3X	20	Negative
2	Controls		20 mg.	Fed 2X	20	Negative



In the first 2 groups we again found some evidence of immunity in the vaccinated calves. In 3 instances the lesion was limited to cold abscess formation, with no lesion in 1 calf and lesions in the regional lymph node in but 1 calf, whereas in the controls lesions were found in the adjacent nodes in every case except 1, where a cold abscess was present. In the 3d group 0.1 mg. intravenously did not produce lesions, while this dose, as well as 0.01 mg., produced lymph node lesions in the control calves. In both instances 1.0 mg. intravenously in control calves produced lesions in the mesenteric nodes as well as in the broncho-mediastinal nodes, whereas in the vaccinated calves 1.0 mg. produced lesions in only the broncho-mediastinal groups. Complete immunity was apparently produced in the feeding series and in the series where doses of 0.1 mg. and 0.01 mg. were injected subcutaneously, but unfortunately tuberculosis was not produced in the control calves in either of these series.



INTRAPERITONEAL VACCINATION

Guinea Pigs—The series consists of 2 groups of 6 animals each:

Guinea Pigs			
3	25 mg.		Living 30 weeks
1	25 mg.		Killed 29 weeks; tubercle spleen
1	25 mg.		Killed 29 weeks; caseous node, small tubercle spleen, liver
1	50 mg.		Living 30 weeks
		Re-vaccination	
1	25 mg.	8 weeks 25 mg. subcut.	Living 20 weeks
1	25 mg.	8 weeks 25 mg. subcut.	Died 13 weeks; secondary infection; tubercles mesenteric nodes
1	25 mg.	8 weeks 25 mg. subcut.	Killed 19 weeks; tubercles omentum
1	25 mg.	8 weeks 50 mg. subcut.	Living 20 weeks
1	25 mg.	8 weeks 50 mg. subcut.	Died 16 weeks; secondary infection
1	25 mg.	8 weeks 50 mg. subcut.	Living 20 weeks

In this series 2 guinea pigs died at 13 and 16 weeks after a second vaccination, the vaccinations being only 8 weeks apart. In the first of these guinea pigs there were histological tubercles in the mesenteric nodes containing infrequent acid-fast rods. In both animals there were extensive peritoneal adhesions with foci of acute abscessation in the nodes, spleen, liver and omentum, but normal guinea pigs injected with triturates of the viscera and nodes of each failed to develop tubercu-

FIGURES V and VI—Tubercles of abdominal lymph nodes of guinea pigs vaccinated subcutaneously 10 weeks previously with 25 mg. of BCG. Ziehl-Neelson stain × 1,140.

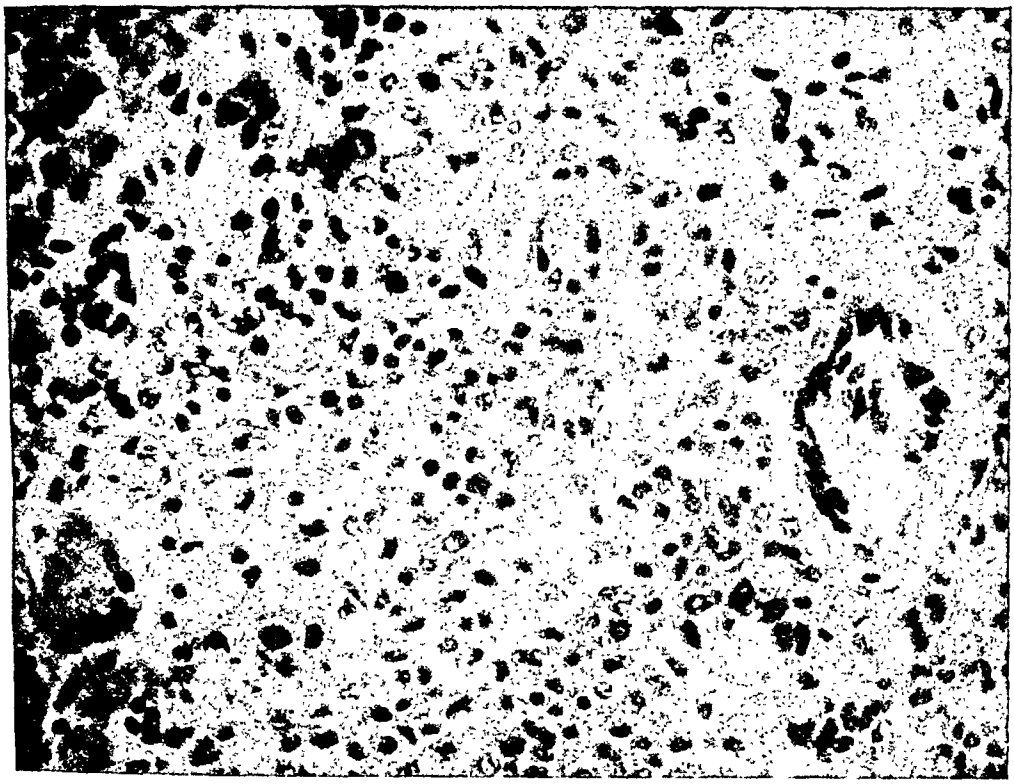


FIGURE VII—Tubercle in spleen of guinea pig vaccinated subcutaneously 10 weeks previously with 25 mg. of BCG. Ziehl-Neelson stain. × 510.

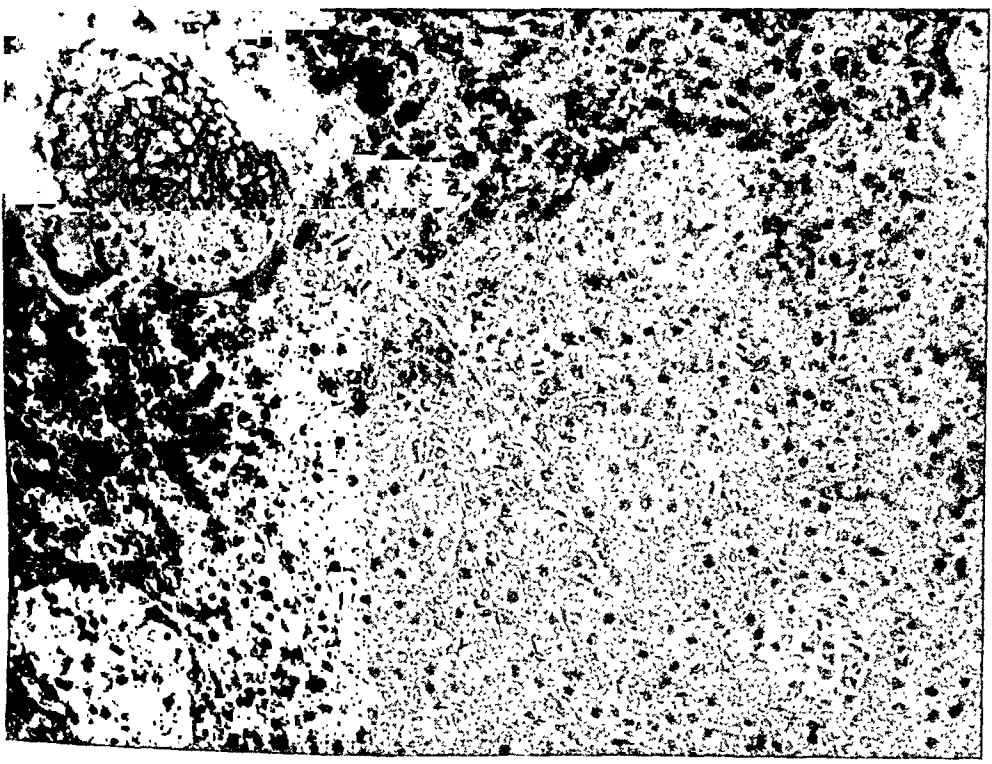

FIGURE VIII—Tubercles in liver of guinea pig vaccinated subcutaneously 10 weeks previously with 25 mg. of BCG. Ziehl-Neelson stain. × 275.

losis. It seems likely here that massive injections of the BCG so lowered the resistance that the guinea pigs developed secondary infections. Two of the 3 which were killed had only small discrete tubercles, while the 3d had also caseous omental and peritoneal nodes. Each of these guinea pigs had a few peritoneal adhesions.

INTRAPERITONEAL VACCINATION FOLLOWED BY INFECTION WITH VIRULENT BACILLI

Guinea Pigs—This series consists of 3 groups of guinea pigs which received subcutaneously 50 mg. each of the BCG vaccine, with the exception of the first guinea pig which received 25 mg.

Guinea Pigs	Interval	Infecting Dose		Result
1	10 months	0.3 c.c. human	Killed 33 weeks	Tuberculosis of viscera
1	3 months	0.2 c.c. human	Died 39 weeks	Tuberculosis of viscera
1	3 months	0.2 c.c. human	Killed 9 weeks	Tuberculosis of spleen
1	Control	0.2 c.c. human	Killed 16 weeks	Massive generalized tuberculosis
1	Control	0.2 c.c. human	Died 12 weeks	Massive generalized tuberculosis
1	Control	0.3 c.c. human	Died 10 weeks	Massive generalized tuberculosis
1	3 months	0.1 mg. bovine	Killed 33 weeks	Tubercles in nodes, spleen
1	3 months	0.01 mg. bovine	Killed 33 weeks	Tubercles in nodes, spleen
1	Control	0.1 mg. bovine	Killed 33 weeks	Massive generalized tuberculosis
1	Control	0.2 mg. bovine	Killed 33 weeks	Massive generalized tuberculosis
1	13 weeks	0.3 c.c. trit.	Died 20 weeks	Pneumonia; tuberculosis
1	13 weeks	0.3 c.c. trit.	Killed 34 weeks	Few discrete tubercles of spleen, liver and lung *
1	Control	0.3 c.c. trit.	Died 14 weeks	Generalized tuberculosis
1	Control	0.3 c.c. trit.	Died 22 weeks	Generalized tuberculosis

* Three guinea pigs were injected with triturates of spleen and nodes of this guinea pig. All were negative when killed after 20 weeks.

In summarizing this small series it is evident that in the first and last groups the vaccinated guinea pigs developed less extensive tuberculosis and in general outlived the controls. The last group is interesting in that the virulent human bacilli used for inoculation were obtained from the triturate of a vaccinated guinea pig killed 10 months after infection. Therefore, the human bacilli used for inoculation in the last animal in the 3d series had had a total residence of 74 weeks in vaccinated guinea pigs, and upon subinoculation they failed to infect 3 normal guinea pigs.

TUBERCULIN REACTION

We were unable to produce skin hypersensitiveness in 54 new-born guinea pigs and calves which were fed the vaccine. This is not in accord with the findings of Calmette.

Thirty-five of a series of 46 subcutaneously vaccinated calves had positive tuberculin reactions from 8 to 12 weeks later, but by the 32d week 27 of a group of 29 of these had lost their hypersensitiveness.

Sixteen of 23 guinea pigs and 9 of 10 monkeys were hypersensitive at 8 weeks after subcutaneous vaccination, and 16 of 19 guinea pigs were allergic 19 weeks after intraperitoneal vaccination.

In brief, 75 of 97 subcutaneously or intraperitoneally vaccinated guinea pigs, calves and monkeys developed positive tuberculin reactions, whereas 39 new-born guinea pigs and 15 new-born calves did not become allergic after being fed the vaccine.

SUMMARY

We were able to produce small discrete non-progressive tubercles in guinea pigs and monkeys which were vaccinated subcutaneously and intraperitoneally. In no instance were these lesions reproduced upon guinea pig subinoculation. After subcutaneous injection of the vaccine we were able to demonstrate progressive tuberculosis in 1 guinea pig. We are unable to account for this occurrence but suggest that it depended upon some individual susceptibility of the animal.

In 3 instances death from secondary infections has occurred in subcutaneously vaccinated guinea pigs, and in these animals we were able to find more than the usual discrete tubercle formation which has been the characteristic lesion produced by the BCG. The lesions here were modified by the secondary inflammatory changes, and triturates of these tissues when injected into normal guinea pigs failed in every instance to produce tubercles. These guinea pigs were injected with large doses of the vaccine and it seems likely that there is a danger of lowering the general resistance of the animal by massive injections of the BCG.

The results in the attempt to vaccinate animals subcutaneously were suggestive. While vaccinated animals which were later infected with virulent organisms as a rule developed more or less progressive tuberculosis, they generally developed the disease to a lesser extent than non-vaccinated controls which received the same injections of virulent organisms.

So far as the feeding results go in new-born guinea pigs and calves, no evidence has been shown of infection with the vaccine nor of protection by it in the guinea pigs. Two of 8 calves in this group did, however, show evidence of protection. In fairly young but not new-born monkeys, on the other hand, there was evidence of slight absorption; 4 monkeys out of 9 which were fed the vaccine were found at autopsy to have localized tubercles, usually in the mesenteric nodes. These findings indicate that the bacilli in the vaccine may pass the mucous membrane of the intestinal tract of monkeys. The fact that inoculation of these tubercles into normal guinea pigs failed in every

case to infect indicates the successful attenuation of our BCG cultures when grown continuously on the bile medium of Calmette. However, we do not feel justified in drawing conclusions as to the absolute safety of the BCG vaccine until further experimentation has been done covering a period of years on vaccinated animals. We cannot emphasize too strongly the importance of continuous cultivation of the BCG on the bile medium.

The impossibility of infecting normal calves with feeding of what we considered infective doses of virulent cultures shows the absolute necessity of sufficient controls; without these we would have believed that the lack of infection in the vaccinated animals indicated immunization, when it simply showed the difficulty of infecting them through the intestinal tract.

It is interesting to note that none of the guinea pigs and calves fed the vaccine developed hypersensitiveness to tuberculin, while a large majority of those receiving the BCG subcutaneously and intraperitoneally became allergic. The hypersensitiveness usually appeared by the 8th week and seemed to last on an average from 6 to 10 months. In monkeys, in contrast to guinea pigs and calves, the bacilli in the vaccine passed the intestinal mucosa, and produced hypersensitiveness and localized tubercles in the mesenteric nodes. We feel certain that the positive findings in the orally vaccinated monkeys arose from the BCG, since 24 normal control monkeys failed to react to tuberculin and were negative at autopsy.

Ultra-Violet Ray Therapy and Public Health Clinics*

HENRY J. GERSTENBERGER, M. D., FELLOW A. P. H. A.

Director of Pediatrics, Babies and Children's Hospital, Cleveland, O.

ULTRA-VIOLET ray therapy as it is generally used today consists in exposing for varying periods of time a greater or lesser area of uncovered skin to artificially produced radiant energy, containing in addition to other rays those having wave-lengths measuring from 2,900 to 3,100 Angstrom's units (A. U.), and being of an intensity sufficient to produce an erythema.

The two practical artificial sources of these rays in general use at the present time are the quartz enclosed mercury vapor arc lamp and the unenclosed carbon arc lamp. In the form in which industry has made them available for use in home and office practice the quartz mercury vapor arc is the more bountiful source of these special rays. However, by replacing the core of the carbon sticks with minerals such as iron, aluminum and nickel and by using a greater amperage it is possible to obtain from such carbon arcs a quantity of the 2,900 to 3,100 Angstrom's wave-length rays equal to that produced by the quartz mercury vapor arc lamps.

The carbon arc, in addition to these rays, produces in much greater quantities luminous and infra-red rays, the former and some of the latter of which are considered by Sonne and others to be responsible for some of the beneficial results generally credited entirely to the ultra-violet rays.

A priori, one would imagine that a source of radiant energy giving off a light whose spectrum corresponds closely with that of summer sunlight would have therapeutic advantages over any other kind of artificial light. This idea would seem to be substantiated by the opinion rather generally held by men who are treating tuberculous patients; namely, that sunlight as a therapeutic agent is decidedly superior to any artificial source of radiant energy. It should be kept in mind, however, that when an individual is exposed out-of-doors to the rays of the sun he is at the same time being subjected to a variety of

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

additional climatic factors which in themselves may be of great influence in improving the condition and resistance of his body. Consequently, it is possible that, after all, the beneficial therapeutic effect derived from sunlight is principally or even solely due to the action of the narrow band of ultra-violet rays above referred to. This conclusion, however, apparently has been proved to be applicable to but one disease, rickets. A. F. Hess and others having found by the use of filters that rays of wave-lengths of 3,200 Angstrom's units and above have no antirachitic value, while those of 3,100 to 2,890 Angstrom's units have. For tuberculosis and other diseases, such as anemia, respiratory tract infections, chorea, pertussis, etc., such a specific finding has not been satisfactorily made.

Webster, Colebrook, Eidinow and Hill, however, have shown that doses of ultra-violet rays which produced erythema increase the non-specific bactericidal power of the blood for a period varying from 1 to 4 hours. They obtained some evidence of a preliminary stage of depression of the hemo-bactericidal power ½ hour after exposure. They state that absorption into the blood of the products of tissue damage or the enhanced absorption of normal tissue products produced by such damage with the consequent erythema and edema appears to be a natural excitant of immunizing mechanisms, whether the damaging agent be ultra-violet rays, visible rays, dark heat or blistering agents. In some cases they found, when large areas and intense dosage were utilized, a decided fall in the bactericidal power. They conclude that the intensity of the erythema produced and the surface area of skin irradiated per kilogram body weight control the bactericidal response of the blood to irradiation of the skin.

Whether the improvement which, according to most observers, follows ultra-violet therapy in peritoneal and glandular tuberculosis and in scrofula is due to products of tissue damage, or whether it is produced by the absorption of some photosynthesized product other than irradiated ergosterol, or whether both or still other factors are responsible, is impossible to state. Our own experience with the use of ultra-violet rays in the treatment of pulmonary tuberculosis, especially of the types characterized by lobar exudates, even when they proceed to cavity formation, has been surprisingly good, and much better than reported in the literature. However, a speedy cure following exposure to ultra-violet rays such as is regularly witnessed in rickets is not seen in tuberculosis, except in the rarest instances.

Inasmuch as no specific ultra-violet ray deficiency disease except rickets has been established so far, it is necessary to assume that all beneficial effect of irradiation in other conditions or diseases is due to the development and action of one or more non-specific factors.

This fact limits scientifically preventive ultra-violet therapy to rickets. This disease, however, is quite as satisfactorily prevented and cured by the use of the more economic and old-fashioned cod liver oil or by the ingestion of small doses of the modern irradiated ergosterol. Consequently, there is no justification for establishing ultra-violet ray clinics for the prevention of this disease.

It should be stated at this point that it has been demonstrated that the antirachitic value of irradiated material can be reduced and completely destroyed by further and excessive exposure to the quartz mercury vapor arc, and also that animals can be killed by giving irradiated ergosterol in too liberal quantities. Both of these observations indicate that great caution must be exercised both in its preparation and in its use.

As ultra-violet therapy has not been proved to be a specific agent in the cure of tuberculosis, anemia, respiratory infections, etc., and as it is known that these diseases develop in individuals who have had the benefit of their use, and as the disease which is specifically cured by the ultra-violet rays, namely, rickets, has not been demonstrated to be present in those above the age of 3 years, it would seem unwise to advocate at this time the general establishment by public health departments of the rather expensive ultra-violet ray clinics for the prevention of disease. I come to this conclusion in the face of my own conviction, based upon clinical experience, that the exposure to ultra-violet rays, properly managed, is of value not only to infants but to children and adults during the winter months in those parts of the country where climatic conditions make impossible an adequate exposure of the individual's skin to ultra-violet rays.

I see no objection, however, to collecting observations on a big scale, over a period of 5 to 10 years, on the efficacy of ultra-violet ray exposures on the general health of school children. If half of the school children for 5 consecutive years can be exposed in a minimal fashion and under proper supervision to the ultra-violet rays, while the other half remains unirradiated, evidence may be obtained which will justify the expenditure of funds coincident with the establishment and operation of ultra-violet clinics.

Another reason for hesitating to advocate at this time the use of ultra-violet ray therapy by public health clinics in the prevention of disease is the fact that we probably know but little concerning the functions of the radiant energy produced by the lamps under discussion. In a statement prepared by the Council on Physical Therapy of the American Medical Association for the Scientific Exhibit at the Minneapolis meeting, it was emphasized that:

Before light can be used therapeutically with the best results, its relation between effect and wave-length must be well understood. Thus far, probably but one of the physiological effects of radiant energy has been studied with a desired thoroughness, namely the effects of visible light in arousing the sensation of vision. The efficiency of the human eye has been accurately determined by the different wave-lengths in the visible zone of the spectra, and a curve called the luminosity curve has been plotted showing the variation of efficiency with wave-length. Not only does this curve vary with different persons but it also shifts with a change in the intensity and the spectral energy distribution of the source of light.

In his address at the last meeting of the American Medical Association, Dr. William T. Bovie expressed the same view and emphasized that actino therapy today still is a complicated subject.

In conclusion, let me say that from the standpoint of the best and greatest development of preventive medicine it is my conviction that scientifically established facts, adequate clinical substantiation of their practical value and conservatism should be the guides of a health agency in determining its course of action in actively furthering the prevention of disease.

Swiss Law Requires Measures Against Tuberculosis

SWITZERLAND'S Federal Law of June 13, 1928, requiring measures for the prevention and cure of tuberculosis is soon to go into effect. Heretofore, certain cantons and municipalities have had regulations for this purpose, but this is the first time that comprehensive measures on a national scale have been prescribed.

The law requires that all cases of tuberculosis in a contagious stage be reported to the government by the attending physicians and that medical supervision be given children and teachers in all schools, asylums, and similar institutions. Any pupil or teacher with tuberculosis in a contagious stage is to be removed from the school or institution, and when necessary is to be given free treatment.

The cantons are required to take certain measures for the prevention and treatment of tuberculosis, such as establishment of health centers, vacation camps for children predisposed to tuberculosis, preventoriums, convalescent homes, and sanatoriums. The law also requires the cantons to see to it that employment agencies for tuberculous patients are established wherever necessary.

Detailed regulations are prescribed for housing and public hygiene and for education of the public in personal hygiene. The work of enforcement is to be carried out by the federal government, the cantons, and the municipalities, in coöperation with private agencies. The cost of the work is to be met by the federal government and by the cantons.—*Bull. des Eidgenossischen Gesundheitsamtes,* Bern, No. 31, 1928, supplement.

The Effect of Various Types of Shoes upon the Feet and Posture of High School Girls*

IZA WHITE MERCHANT AND KATHERINE CRANOR

Department of Home Economics, Iowa State College, Ames, Ia.

AN experiment to determine the effect of various types of shoes upon the feet and posture of high school girls was carried on by the authors in coöperation with the departments of physical education of the high schools of Ames, Ia. Three hundred and sixty-eight high school girls participated in the experiment.

Shoes were examined as to type, and measured; feet were measured and examined for defects; and footprints were taken.

To determine the relation of posture to shoes, schematograph pictures of back and side views were made of 167 senior girls.

X-ray pictures were made of normal and defective feet with and without shoes, and of feet when both low and high heels were worn. X-rays were also made to determine the effect of high heels upon the position of the bones of the pelvic region.

Posture defects noted among 42 girls wearing high heels:

36 neck bent forward
32 protruding abdomen
42 narrow curve between shoulder and hip

X-ray pictures indicate a tilt of 40° in pelvis when extremely high heels were worn, muscles in upper leg not exercised, muscles in lower leg over-exercised, shape of leg spoiled by the muscles being pushed to back of calf.

Posture in every instance was better in bare feet than with high heels. Eighty-nine per cent of the girls having good feet had good posture.

In every instance, where a girl had one high hip and one high shoulder, she was found to have an overdeveloped foot on the opposite side.

COMPARISON OF RESULTS

	1927 Per cent	1928 Per cent
Girls wearing oxfords	60	80
Shoes short and narrow	77	20
Poor longitudinal arches	72	60
Poor transverse arches	90	80
Flat feet	40	10
Rotating heels	62	55
Corns or callous	54	78
Normal feet	1	3

Improvement noted in the choice of shoes over those of 1927 was 37 per cent. Of last year's girls there were 14 per cent who had improved the condition of their feet. The girls whose feet were outstandingly good or bad last year are the same ones this year.

* This is an abstract of a monograph published by the authors. It also gives additional material which was discovered in the continuation of the study begun in 1927.

WORLD HEALTH CONDITIONS

THE annual report which the Surgeon General of the U. S. Public Health Service has just submitted to Congress is interesting on account of the summary of world conditions which it gives, and also as it demonstrates once again the high degree of protection given to the people of this country by that service. Not only does the service gather knowledge daily as to the prevalence of communicable diseases in every part of the world, but there is also medical examination of immigrants about to sail for this country and inspection of the vessels and seamen, in addition to which a second medical examination must be undergone at the port of arrival. During the year no case of any quarantinable disease was brought into our country.

In general the past year has been a favorable one in regard to health. There were no great epidemics, and the efficiency of modern health organization was demonstrated by the fact that in no country in which such organization has been established has there been an outbreak of any of the diseases which in the past we have had so much cause to fear.

Bubonic plague still appears to be the disease which is our chief menace, India being the great potential focus of infection. However, cases were reported from French Indo-China, China, Algeria, Madagascar, Nigeria, Siam, Argentina, Ecuador, South Africa, Greece and Russia. Two cases, contracted from ground squirrels, occurred in California, the only ones reported on the North American continent.

Yellow fever, apparently of a peculiarly virulent type, occurred in a number of places in Africa, especially along the west coast. Of more direct interest was the fairly extensive epidemic in Rio de Janeiro, beginning in May, 1928. The case fatality rate was 55.5 per cent.

Smaller outbreaks occurred in some other South American ports and interior cities.

While typhus fever has not been unduly prevalent in Europe, recent studies show that it is endemic in the United States, especially along the Atlantic seaboard and in the lower Rio Grande Valley. Fortunately it is of a mild type.

Smallpox continues to be a blot upon our record. Approximately 34,000 cases occurred in the United States in 1927. With the exception of India, we lead the world in this respect. Certainly there is a call for especial activity on the part of health officers and health workers to combat the false ideas which are constantly being put forward in regard to vaccination, as well as the apathy of the public in regard to this simple, safe and efficient preventive.

Attention is called to the death rate from two diseases which are too generally considered insignificant, and necessary to childhood—measles and whooping cough. In the reporting states, some 4,000 deaths occurred from measles and 7,000 from whooping cough during the year 1927, figures which prove that these diseases call for care and are not to be regarded as trivial.

The work of the Service in keeping in touch with world conditions has been tremendously aided by the Health Committee of the League of Nations, and as far as the Eastern countries go, by the establishment of a reporting station at Singapore. This station collects information from India, China, Japan, the Malay states, the Philippines, Borneo, Australia and the east coast of Africa. It is cabled weekly to Geneva, where it is combined with similar reports from Europe and America, and the final results relayed to all parts of the world.

Those who keep in touch with the *Public Health Reports* are more or less familiar with many of the facts contained in the interesting report of the Surgeon General, which, however, summarizes the information from all parts of the world for the entire year.

METHODS OF SECURING THE 1930 CENSUS BY SANITARY AREAS FOR CITIES

AN increasing interest, on the part of health officers and executives of volunteer health agencies of cities, in the permanent area basis for enumeration of city populations has developed with the approach of the 1930 decennial census.

The procedure necessary to obtain this from the U. S. Bureau of the Census is simple and should be understood by those concerned with

the accurate analysis of such health and social problems of their communities as depend for their solution upon complete data regarding the population in small areas with permanently established boundaries.

New York, Cleveland and St. Louis are the only cities which have availed themselves of the willingness of the U. S. Bureau of the Census to assist communities in obtaining neighborhood facts.

Although New York (which furnished a map for the 1910 Census) was the only city that furnished the Bureau with permanent maps for the taking and tabulation of enumeration data, the Bureau, of its own motion, subdivided the political units used by itself for publication purposes into census tracts, in the case of all cities of 500,000 population and over, and the tabulated results were and are at the service of local committees who will undertake their transcription for publication. In 1920 this service was repeated.

New York's population of 1910 was tabulated and the data were published by the Cities Census Committee in terms of 707 neighborhood units. Its map of 1920, with an increase to 3,427 units resulting from the subdivision of all areas of over 80 acres, was the basis of 1,630 neighborhood tabulations by the Bureau and of their publication by the coöperating New York committee.

The map of 1920 is New York City's permanent map for neighborhood census enumeration and tabulation, and one of the functions of its local committee, essential to the system, is to keep the same up to date as to street nomenclature and layouts, and to furnish the Bureau, on the eve of every census, with accurate maps, in sufficient quantity, for actual enumeration.

Chicago, Cleveland, Detroit, St. Louis, Pittsburgh, Boston and any other city anticipating the benefits of a permanent area basis for its 1930 enumeration and tabulations, must furnish the Geographer's Division of the U. S. Bureau of the Census with a uniform area unit map which will register the community's own drafting of its neighborhood boundaries. While New York City's census tracts, or sanitary areas as they are commonly called, are of approximately 40 acres each, probably an area of 160 acres for each such unit would serve the purpose satisfactorily in other cities.

This primary procedure in order that any city may receive the benefit of a permanent area basis for its enumeration and tabulations is necessary because of the extensiveness and complexity of the tasks of the Geographer of the Census. He must assemble, or prepare, for every square foot of the continental area of the United States and of its outlying possessions the office and field maps which are indispensable requisites for the 1930 Census.

To have ready for the portfolio of each of the 100,000 or more enumerators likely to be engaged in the 1930 Census, a map of the territory to be covered by him, and to be sure when all the portfolios have been distributed that no area of human habitation has been omitted, is a Herculean task. If to this the cities of the nation, desiring tabulations of neighborhoods smaller than those essential to the Bureau's own publication plans, add the task of subdividing their areas into permanent units for supplying them with information more detailed than the resources of the U. S. Bureau of the Census allow it to print, they are asking the Geographer to imperil what is imperative in the discharge of his duties, and are, moreover, asking him to perform a task for which the necessary data are not available in the U. S. Bureau of the Census.

One of the publications of the Bureau (*Financial Statistics of Cities having Population of 30,000 or Over*, U. S. Dept. of Commerce, 1925) gives the total area of all cities of 30,000 or over in the United States; but there is no Census publication giving the area of wards or other political subdivisions of cities, and without an area measurement of the units used by the U. S. Bureau of the Census itself, these units cannot be subdivided intelligently for a permanent map.

Experience has shown that there are many cities in the United States in whose engineers' offices cannot be found acreage measurements of the units employed by the Bureau for tabulation and publication purposes, and any city that expects the Geographer of the Census to institute a permanent area basis when the data requisite therefor are not in existence, is expecting too much.

A worker in Washington, moreover, cannot be expected to be so minutely familiar with the topography of all American cities as to be able, even when ward or other acreages are known to him, to subdivide such acreage into units most usable for the local community. This is a job suitable for a local committee.

These considerations compel the preparation, by any city desiring a permanent area basis, of a neighborhood map in which the entire area of the city is divided by established street boundaries into 160-acre tracts or multiples of them, using the official map of the city as the basis therefor. This map must be registered before July 1, 1929, with, and be accepted by, the Geographer of the Census for the taking and tabulating of the Census of 1930.

Any city which does not take this step deliberately excludes itself from participation in any tabulation of its population other than that required for the U. S. Bureau of the Census for its own purposes.

This, however, is not the whole of the matter. In a recent com-

munication to the coöperating New York committee the Director of the Census says:

> I have given instructions that the tract system shall be abandoned unless the cities (i.e., through some organization of authority) give us a definite promise that the material will be utilized somewhat as you utilized it for New York. The tabulating of this great mass of detailed material by tracts and then laying it aside is, to my mind, a wasted effort.

A city, therefore, desiring the benefit of a permanent area basis for neighborhood tabulations of its population must not only equip itself with some kind of organization which will prepare for the Geographer's Division a map which will enable that division to take the enumeration in such wise that the tabulation can be produced, but must be able to assure the Bureau that the tabulation when produced will be transcribed for publication by a local committee in such wise as to meet the needs of neighborhood population survey and service in its local community.

The Cities Census Committee, Inc., 200 Fifth Avenue, New York, N. Y., which exists primarily to secure to New York City, and cities of 100,000 in its immediate neighborhood, the benefit of a permanent area basis for population enumeration and tabulation, and whose charter permits it to assist other cities of similar size in securing the same benefits, puts its experience at the disposal of all communities interested in this subject.

ASSOCIATION NEWS

A. P. H. A. ACKNOWLEDGES INTEREST OF STATE HEALTH PUBLICATIONS

The Association wishes to express its appreciation to the many state and local health departments who have aided in disseminating information of the activities of the Association, especially through the columns of their weekly and monthly health bulletins. The New York State Department *Health News* recently carried an article on "The Appraisal Form for City Health Work, 3d Edition, 1929," which brought this new volume to the attention of many health workers who might not otherwise have been reached. Likewise the Christmas issue of the West Virginia *News Letter,* published semimonthly, offered its coöperation by publishing the "Season Greeting" sent out by the Committee on Administrative Practice, A. P. H. A.

DR. DAVIS DIES OF HEART ATTACK

William H. Davis, M.D., chief statistician of the Bureau of the Census, Washington, D. C., died January 8 in Washington of a heart attack while ill with influenza. Burial was in Washington, January 11.

Dr. Davis was an untiring worker in the Association, having served as vice-president during 1923–24 and taken an active part in the program of the vital statistics section. At the time of his death he was chairman of the Committee on Forms and Methods of Statistical Practice.

MISS JEAN GOES TO THE ORIENT

Sally Lucas Jean, health education consultant and one of the organizers of the Child Health Organization and later director of the health education division of the American Child Health Association, sailed January 12 from Seattle for the Philippine Islands where she will develop a health education program in the schools at the request of Governor-General Henry L. Stimson. Miss Jean will inaugurate the program which will be carried out over a 2-year period by Miss Edna Gerken, supervisor of health education, Fall River, Mass. Miss Jean will spend several weeks in Japan conferring with educational and health authorities, and in Hawaii she will represent the American Public Health Association.

Miss Jean is a member of the Advertising Committee of the A. P. H. A., the Committee on Exhibits, and of the recently organized Committee on Cooperation, Development and Finance.

DR. GOLDBERGER DIES IN WASHINGTON

Dr. Joseph Goldberger, 55, world famed scientist, discoverer of the cause of and cure for pellagra, and a Fellow of the A. P. H. A., died January 17 in the U. S. Naval Hospital in Washington, D. C., following a long illness. The cause of Dr. Goldberger's illness had been undetermined, but an autopsy showed that all his vital organs had been attacked by a malignant growth.

Dr. Goldberger was born in Austria-Hungary and came to this country when he was 7 years old. He received his medical education at Bellevue Hospital Medical College and later interned at that hospital. He practiced in New York City and Wilkes-Barre prior to entering the U. S. Marine Hospital Service, which later became the U. S. Public Health Service.

Three times Dr. Goldberger's life was endangered, once while he was on duty

at the American Consulate in Tampico, Mex., when he contracted yellow fever, again when he was studying typhus fever in Mexico City, and another time while he was investigating an epidemic of dengue fever.

Fourteen years ago Dr. Goldberger began his research work in pellagra which resulted in his conclusion that pellagra is caused by improper diet and can be cured by correct diet.

In commenting upon his death Assistant Surgeon General Kerr said that Dr. Goldberger's experiments had been of great economic importance to the country and that his contribution compared with that of Dr. W. C. Stiles, who discovered the cause of hookworm infection, and Dr. Walter Reed, who discovered yellow fever.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Conference on Influenza, January 10, 1929—A conference was called by Surgeon General Hugh S. Cumming in Washington, D. C., to discuss the influenza situation. This conference was attended by approximately 100 representative physicians and public health workers from all parts of the country. The resolutions adopted at the conference were drafted by three committees appointed for this purpose. One committee dealt with scientific research, a second committee dealt with preventive measures, while the third committee discussed epidemiological studies.

The following is the report of the committee on preventive measures:

REPORT OF COMMITTEE ON PREVENTIVE MEASURES

When influenza is prevalent or is believed to be approaching a community, during the course of an epidemic it is advisable to take advantage of the public interest and concern by emphasizing anew those public precautions and practices of personal hygiene upon which the prevention of communicable affections of the upper respiratory tract depends.

Measures for precaution fall naturally under those of a communal or administrative character and those which apply to the individual:

I. *Communal or Public Precautions*

1. Efforts should be made to reduce the opportunities of direct contact infection by avoiding crowds.

2. Schools or colleges should not be closed wherever adequate medical and nursing supervision is available and provision is made for the prompt exclusion of all persons showing suspicious catarrhal symptoms, especially when these are associated with a rise of temperature.

3. The reopening of boarding schools and colleges after vacation should not be encouraged in the presence of epidemic influenza unless there are generous accommodations for the bed care of those who may be attacked.

4. While the general closing of places of public assemblage is to be deprecated, there may be local conditions justifying such action at the discretion of the local health authorities.

5. In groups which can be brought under daily professional inspection the isolation of early and suspicious cases of acute respiratory tract infection, particularly when these are accompanied by rise in temperature, may result in delaying the spread of the disease.

6. In isolated communities and in institutions infection may be delayed and sometimes avoided by the strict exclusion of visitors.

7. The person and sick room of an infected individual must be considered a definite focus of infection, and visitations to such persons or premises should be avoided by all persons except the necessary medical and other attendants.

II. *Education in Cleanly Personal Habits*

When influenza prevails or threatens, information on the subject of cleanly personal habits and personal hygiene should be spread widely, particularly with regard to the following points:

1. Avoidance of all uncovered acts as in coughing, loud talking, sneezing or spitting.

2. Special emphasis upon the need of washing the hands frequently, more especially before eating; unclean articles and fingers should be kept out of the mouth and nose. This advice is particularly applicable to all persons in attendance upon the sick.

3. Avoidance of exposure, fatigue and any bodily excess.

4. Persons in good health should continue in their normal manner of life.

III. *Advice to Individuals for Guarding against Colds, Upper Respiratory Infections and Influenza*

It would seem advisable that in the presence of influenza or upper respiratory infections individuals should make more than the ordinary effort to increase well-being. This may be obtained by:

1. Securing adequate sleep and rest (8 to 10 hours' sleep every night with windows open, but under enough covering to keep warm).

2. Eating a moderate, mixed diet and partaking freely, at regular periods, of pure water (6 to 8 glasses daily).

3. Wearing clothing to suit the environment, particularly clothing which prevents chilling of the body surfaces and which keeps the body dry.

4. Avoiding people with colds, especially those who are sneezing or coughing. There is more danger from contact with those just beginning to feel sick than from those ill enough to be confined to bed.

5. Keeping out of crowds so far as possible, especially crowds in closed places.

6. Avoiding the use of common towels, wash basins, glasses, eating utensils, and toilet articles.

7. Washing the hands thoroughly before eating.

8. Avoiding the use of any so-called preventives. Vaccines, serums and advertised preventives seem to be of no value and may be harmful in this disease.

9. Avoiding alcohol and stimulants of all sorts.

IV. *What to do to Prevent Becoming Seriously Ill if You Get the Disease*

1. If you have a cold, feel ill, or are feverish, go to bed at once, cover up warmly and have the windows open; send for a physician and follow his instructions.

2. Do not take any so-called cures. There is no specific cure for this disease.

3. If you cannot get a doctor, remain in bed, eat a simple diet, take plenty of fluids, such as water, fruit juices, milk, bouillon, hot soups, at frequent intervals. Use a mild cathartic, if constipated.

4. Remember that the most important measure of preventing pneumonia or other serious complications is to remain in bed until all symptoms have disappeared and then, under the physician's advice, to return very gradually to your usual physical activities, being sure to rest before you get tired.

Scarlet Fever—In 1925, 2,124 children in the Michigan Home and Training School were tested by the Dick method and 37.6 per cent found positive. These were immunized with 500 skin test doses followed by 1,000 to 1,500, and as a 3d dose 3,000 to 4,500. A re-Dick test 21 days later showed 61 per cent still positive. To these a 4th dose of 5,000 skin test doses was given. Fourteen days later 11 per cent were found positive. Additional doses were given until all cases except those lost track of gave negative Dick test. Three years later a retest of 577 of the original 799 children indicated that 29.3 per cent had changed from negative to positive.

In a smaller group immunized in 1926 with larger doses, it was found that 34 per cent had become positive by May, 1928. Although scarlet fever did appear among children later admitted to the institution and used as controls, and did in one instance occur in a child which had given a negative Dick test, the officers of the institution have concluded that scarlet fever has been controlled by such immunization. Since January, 1927, there has been no scarlet fever in the institution in which prior to the initiation of immunization scarlet fever was almost constantly present. The Michigan Department of Health has also used active immunization to prevent scarlet fever in other state institutions and with the coöperation of local physicians and health officers has given 8,000 1st doses and 6,900 3d doses in some 125 towns scattered throughout the state. Reactions have been watched very closely. About 7 per cent of susceptible persons treated will develop nausea after the 2d or 3d dose; about 4 per cent nausea, vomiting and purging, and about 2 per cent nausea, vomiting, purging and rash. The reactions are those of toxemia and are transitory,

seldom lasting more than 24 hours.—Guy L. Kiefer, The Value of Active Immunization against Scarlet Fever, *J. A. M. A.*, 91: 1885 (Dec. 15), 1928.

Infantile Paralysis in Massachusetts—In 1927 there were reported 1,189 cases of infantile paralysis in Massachusetts. The Harvard Infantile Paralysis Clinic at the Children's Hospital has been treating 636 of these cases, more than half of the total number. The epidemic affected the eastern part of the state, there being 277 cases in Boston and 111 cases in Haverhill. The incidence rate in Boston was 0.35 per 1,000, in Haverhill it was 2 per 1,000, while in Ipswich, a small town thirteen miles east of Haverhill, there were 26 cases with an occurrence rate of 4 per 1,000. The death rate in the 1927 epidemic was 14.2 per cent compared with death rates of 23.5 in 1916 and 20.7 in 1920. The average age of the patient was 5.4 years. Instances of more than one case in the same family occurred 32 times in 755 families, or 4.2 per cent. One family in Haverhill had 4 children affected, in 2 of whom the disease proved fatal.—A. T. Legg, An Analysis of the 1927 Epidemic of Infantile Paralysis in Massachusetts, *J. A. M. A.*, 92: 31 (Jan. 5), 1929.

Whooping Cough—A freshly prepared vaccine was administered to 100 patients subcutaneously. At first injections of 1, 2 and 3 billion of killed *B. pertussis* (Bordet-Gengou) were given at 3-day intervals. Later the dosage was increased to at least 3, 4 and 5 billion bacilli. The vaccine was prepared from newly isolated strains from typical cases. In none of the 100 children was the disease prevented, although quite a number of patients were given the vaccine very early. Five of 6 infants exposed to older patients in their households received 3 inoculations during the catarrhal or early paroxysmal stage, but all developed severe pertussis.

A study of cases indicated that a father, who contracted the disease from his barber, gave it to his 4-year-old son. There is also history of a patient of 6 having had whooping cough twice, the first attack being at the age of 2 years. In the second attack the Bordet-Gengou bacillus was found on the cough-plates.

White and differential blood counts were made on most of the patients. In complicated broncho-pneumonia counts were high but the proportion of lymphocytes was lower. In some mild but unquestionable cases the white cell counts never exceeded 10,000 per cu. mm. In no mild uncomplicated case was the count very high; in no severe case was it low.

Bordet's method of isolating the bacilli was employed. Of 34 cases 97 per cent were positive during the catarrhal stage of the disease. Of 50 cases, 50 per cent were positive in the paroxysmal stage. During the decline of the disease the bacilli were not found in any of 16 cases examined.

The high mortality rate in pertussis patients warrants recourse to all known means of early diagnosis. Infants and very young children should be protected from patients and exposed susceptible children. This can be done only by early quarantine. If health departments would include in their service whooping cough diagnosis by means of the cough-plate, an earlier diagnosis could be made and an earlier quarantine established.—L. W. Sauer and L. Hambrecht, Whooping Cough, *J. A. M. A.*, 91: 1861 (Dec. 15), 1928.

LABORATORY

C. C. YOUNG

FOOD POISONING BY BACTERIAL TOXINS

R. W. PRYER, D. P. H., FELLOW A. P. H. A.

State Department of Health Laboratories, Lansing, Mich.

IN MANY reported cases of food poisoning the rapid onset of symptoms has led skilled investigators to conclude tentatively that soluble, more or less heat resistant, toxins played an important rôle.[1]

The following report of a food poisoning case is believed to be an example of food poisoning by bacterial toxins with a reasonable amount of proof of the probable nature of the infecting organism despite the fact that viable organisms of any of the commonly accepted food poisoning group were never isolated.

In view of certain unusual incidents connected with this case, the two laboratories concerned will be referred to as Laboratory A and Laboratory B.

In March, 1926, a specimen of corned beef was sent in to Laboratory B from one of the smaller cities of Michigan with the information that the attending physician was quite certain that the meat in question had caused illness in a family. Laboratory B referred the letter and specimen to Laboratory A. The director of Laboratory A received the specimen and turned it over to analyst "X" for examination. Analyst "X," becoming convinced from a cursory examination of the meat that it was not the cause of the trouble, ate some of this meat and persuaded 3 others to do the same. As a result of this unofficial act, all 4 were taken ill in about 2½ hours with cramps, vomiting and profuse diarrhea followed by extreme prostration. All 4 were definitely out of danger in 24 hours and the result of the unofficial test was to convince all parties concerned that the offending article of food had been isolated.

The specimen of meat was then turned back to Laboratory B and the remainder of the bacteriological work done at that time was performed by analyst "Y."

The specimen as received by analyst "Y" consisted (as shown by his report) "of ⅝ lb. oblong loaf of corned beef together with fragments contained in large glass jar with clamp cover. Original tin container and lid were also received." Analyst "Y" reports that although "the meat appeared rather dark red in color, no unusual odor was observed." His conclusions after a considerable amount of work were as follows:

An unidentified aerobic streptococcus of the Gamma type (Brown's Classification) was found in large numbers throughout the specimen. A gram positive encapsulated, bile soluble, green producing, lanceolate diplococcus, which is not agglutinated or precipitated by pneumococcus antisera of types I, II and III, believed to be a pneumococcus of type IV, was found in moderate numbers.

Extract from meat specimen was found to contain a non-filterable (Mandler filter) substance toxic to small guinea pigs when injected in moderate to relatively large doses. . . .

The toxic effects produced by this specimen are believed to be due to the presence of an endotoxin in the organisms isolated from the specimen, no soluble exotoxin being demonstrable. This substance is apparently much more toxic for humans than for laboratory

animals, although guinea pigs died following the injection of relatively large quantities of the material. Smaller quantities produced severe but non-fatal toxic symptoms in these animals.

In December, 1927, 21 months after the specimen had been opened and caused these two outbreaks of food poisoning, the writer received this specimen for examination.

From the bacteriological standpoint our findings as far as viable bacteria are concerned agree very closely with those of analyst "Y." However, none of the cultures isolated give any suggestion of toxin production even when grown in corned beef media, and since organisms of this kind are not usually associated with food poisoning, the toxicity of filtrates of the meat was more fully investigated. Repeated cultures on Endo, brilliant green, blood agar and plain agar, both from fresh emulsions of specimens taken from the central portion of the meat and from enrichment cultures after 24- to 72-hour incubation periods, failed to show organisms of the paratyphoid group. It should also be stated that all animals dying from injection of the unfiltered emulsions of this meat were autopsied and blood cultures as well as peritoneal cavity cultures were made with entirely negative results as far as paratyphoid-like organisms were concerned.

In making up emulsions of this meat for animal experimentation, approximately 20 gm. were ground in a mortar with 100 c.c. sterile water and the mixture filtered through coarse filter paper. An emulsion of this strength would surely kill guinea pigs of 250–350 gm. weight in 3 c.c. quantities when injected intraperitoneally. Heating this emulsion did not appreciably affect its toxicity, as is shown in Table I.

TABLE I

Guinea Pig No.	Weight	Amt. Injected I.P.	Previous Treatment of Emulsion	Result
X141	350	3 c.c.	—	Death in >18 hrs.
X144	300	5 c.c.	—	Death in >18 hrs.
X66	250	5 c.c.	heated 70° C. 1 hr.	Death in >18 hrs.
X57	280	3 c.c.	heated 70° C. 1 hr.	Death in >18 hrs.
X74	330	3 c.c.	heated 100° C. 1 hr.	Death in >18 hrs.
#151	250	5 c.c.	heated 100° C. 1 hr.	Death in >18 hrs.

Following filtration through either a Seitz or Mandler filter the toxicity of an emulsion is markedly decreased, but such filtrates have caused death of guinea pigs following intraperitoneal injection.

The possibility of this toxic action being due to metallic substance was ruled out by a chemical examination.

The intravenous injection of rabbits with Seitz filtrates of emulsions of this meat and the titration of the agglutination power of their blood against various members of the paratyphoid group of organisms has given us an idea of the probable nature of the etiological factor concerned.

Rabbit No. V108—The normal blood showed no agglutination when titrated against the following organisms:

Cultures No. 511, 541, 542 *B. enteritidis*
526 *B. aertrycke*
509 *B. suipestifer*
501 Morgan's bacillus
512 *B. paratyphosus C*
B. typhosus
B. paratyphosus A
B. paratyphosus B

After 6 intravenous injections of increasing amounts of the Seitz filtrate of an emulsion of this meat, the serum of Rabbit No. V108 obtained 9 days after the last injection gave results shown in Table II.

This work indicates that the original infecting organism in the meat was one of the aertrycke group which had produced a heat resistant toxin.

Attempts to produce a higher titer serum were unsuccessful although a

TABLE II

	1–10	1–20	1–40	1–80	1–160	1–320
B. typhosus	–	–	–	–	–	–
B. paratyphosus A	–	–	–	–	–	–
B. paratyphosus B	–	–	–	–	–	–
B. enteritidis No. 511	–	–	–	–	–	–
B. enteritidis No. 541	–	–	–	–	–	–
B. enteritidis No. 542	–	–	–	–	–	–
B. aertrycke No. 526	++	++	+	–	–	–
B. suipestifer No. 509	++	+	–	–	–	–
B. paratyphosus C No. 512	–	–	–	–	–	–

number of rabbits were used in the trials.

This work would seem to indicate that the original infecting organism in the meat was either *B. aertrycke* or *B. suipestifer* and that the two outbreaks of food poisoning were due to a heat resistant toxin produced by this organism.

STANDARDIZATION OF THE WASSERMANN TEST*

RUTH GILBERT, M. D., FELLOW A. P. H. A., AND ANNA M. SCHAIBLE

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

FURTHER work was done in the standardization of antigens and complement used in the complement fixation test for syphilis. Since the fundamental basis for precipitation and complement fixation reactions is probably the same and the former test is being more and more extensively used, the comparative value of some of the more widely used precipitation tests was investigated. The results with the Kahn test, which has been given the most extensive study thus far, indicate that although it is somewhat more sensitive than the complement fixation test with the acetone-insoluble antigen, it is much less sensitive than the test with the cholesterolized antigen when the test is carefully standardized and controlled. The Sachs-Georgi and Meinicke tests which have been made are as yet too few in number to permit any definite conclusions. The reactions obtained with the Meinicke test indicate that it compares fairly closely with the Kahn test in sensitivity, while decidedly fewer reactions were obtained with the Sachs-Georgi test. No definite evidence of nonspecific reactions was obtained with any of the tests studied, if they were carefully controlled and the directions of the authors were followed in detail. The desirability of adopting a uniform complement fixation technic is urged, since aside from its chief value in increasing the accuracy of the information furnished the clinician, it would provide a standard for judging the reliability of precipitation and other tests for syphilis.

* Abstract of Referee's Progress Report for 1928 to the Committee on Standard Methods, presented to the Laboratory Section of the American Public Health Association at the Fifty-seventh Annual Meeting in Chicago, Ill., October 16, 1928.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

The 1927 Life Table for American Workers—In 1927 the expectation of life at birth among industrial policy holders of the Metropolitan Life Insurance Company was 56.42 years as compared with 55.02 for 1926. A large part of the gain occurred in the early ages of life. The expectation of life at age 10 for white males was 51.88 as compared with 51.41 in 1926, and 51.63 in 1925. For white females the expectation of life at age 10 was 55.32 in 1927 as compared with 54.87 in 1926. For colored males, the corresponding figures were 44.99 in 1927, as against 44.84 in 1926; for colored females 46.34 in 1927 as against 45.60 in 1926. The expectation of life at age 20 for white males was 42.93 in 1927, and 42.49 in 1926. For white females the expectation of life at the corresponding age was 46.33 in 1927, contrasted with 45.87 in 1926. Among colored males the figures in 1927 were 37.08, and in 1926, 36.80; and for colored females 38.64 in 1927, and 37.97 in 1926. At age 30 the expectation of life among white males in 1927 was 34.44, contrasted with 34.02 in 1926. Among females, it was 38.05 in 1927, and 37.53 in 1926. The expectation of life for colored males was 30.05 in 1927, as against 29.91 in 1926; and for colored females 32.15 in 1927, as against 31.41 in 1926.—*Stat. Bull.*, Met. Life Ins. Co., 9: 2 (Nov.), 1928.

Health Gains among Negroes—A study of 2,500,000 negro Industrial policy holders of the Metropolitan Life Insurance Company showed that between 1911 and 1927 the mortality rate of negroes at all ages dropped 17.3 per cent as compared with 31.6 per cent for whites. The death rate among insured negro children 1 to 14 years of age showed between 1925 and 1927 an improvement of 38 per cent over the 3-year period between 1911 and 1913. The mortality of the whites improved 43.6 per cent for the same period. Between 15 and 24 years of age the negro gain of 28.8 per cent closely approached the 31.9 per cent gain of the whites. After the age of 25 the improvement for the negroes approximated only one-half that of the whites. Between the ages 25 and 34 the negro gain was 24.2 per cent whereas that for the whites was 42.7 per cent, and between the ages of 35 and 44 the negro gain was only 18.1 per cent whereas for the whites it was 39.8 per cent.

The greatest single factor in the improvement of the mortality rate of the negroes for the periods 1911 to 1913 compared with 1925 to 1927 was the decline in the death rate from tuberculosis. While the gain for all causes combined was 17.3 per cent, that for tuberculosis was 44.7 per cent. Among the negroes the greatest decline, 156.5 per cent, occurred in the 1 to 14 year group. The decline among whites for the corresponding group was 59.2 per cent. Between the ages of 15 and 64 years where the bulk of the deaths from tuberculosis takes place, the gains for the colored ranged from a minimum of 35 per cent to a maximum of 52 per cent. Among whites for the same age group the gains ranged from 49.8 per cent to 54.3 per cent.

The tuberculosis death rate among negroes insured in the Metropolitan's Industrial Department for the first 9 months of 1928 was 233.6 per 100,000, while that for heart disease was 233.9.

The tuberculosis death rate for colored policy holders in 1911 was 2¼ times that for heart disease.—*Stat. Bull.*, Met. Life Ins. Co., 9: 3 (Nov.), 1928.

Diphtheria Survey in Connecticut—A study of diphtheria deaths was made from September, 1923, to the end of December, 1926. The study included 370 deaths out of a total of 437 for the period. Of the 370 deaths, 143 were laryngeal in type and 125 of mixed type. More than half or 53.2 per cent of the deaths studied occurred in children under 5 years of age. Seven and three-tenths per cent of the deaths were among children under 1 year of age; 31.4 per cent within the 5 to 9 year age group; and 9.7 per cent within the 10 to 19 year age group.

In only 20 per cent of the 370 cases the doctor was called on the first day of illness. In nearly 40 per cent of the cases he was not called until the fourth day or later. Antitoxin was not always given as soon as the physician was called. Less than two-thirds of the cases received antitoxin on the first day, and no antitoxin was given to 22 of the cases. Of the contacts with the 370 fatal cases of diphtheria, 44.1 per cent were immunized. Thirty-six and five-tenths were not immunized, and in 9.4 per cent of the cases it was not stated whether immunizing treatment was given.—*Conn. State Dept. of Health Report*, 1927, pp. 88–97.

Vital Statistics of England and Wales—In 1927 there was an approximate of 200,000 in the population of England and Wales. There were 654,172 births and 484,609 deaths. The infant mortality rate was 70 per 1,000 births. There were outbreaks of enteric fever which caused an increase in cases from 2,739 in 1926 to 3,533 in 1927. Smallpox increased in prevalence from 10,146 cases to 17,767. In 1926 only 1 case occurred in Wales, whereas in 1927 2,442 cases were reported. Deaths occurred among 49 persons, 35 of whom were unvaccinated. There were 67,757 cases of pneumonia for the year, which resulted in 37,242 deaths. The number of deaths from all forms of tuberculosis was 83,173 as compared with 37,525 in 1926. There were 2,690 deaths in childbirth, and 1,026 of these were from puerperal fever.—The State of the Public Health, *Brit. M. J.*, 2: 753 (Oct. 27), 1928.

Chronic Disease in Boston—A study of chronic disease in Boston was begun June 1, 1927, by the Boston Council of Social Agencies. A survey was made of 4,316 chronic and incurable patients reported by Boston hospitals or social agencies. Between July 1, 1926, and June 1, 1927, 1,863 of the 4,316 patients were in hospitals for chronic diseases, 1,043 in general hospitals and 1,410 under the care of the Community Association and other social organizations. Males totaled 46.2 per cent; females 53.8 per cent. Seventeen and seven-tenths per cent of the patients were under 15 years of age; 7.3 per cent between 15 and 29; 33.6 per cent between 30 and 59; and 41.4 per cent were 60 or over.

There were 845 cases of heart disease, which constituted about one-fifth of the total number of cases. There were 553 patients with organic nervous and mental disease; and 534 with cancer. The chronic arthritis cases numbered 467; 4.9 per cent of these cases were under 20, and 36.4 per cent under 60. The non-pulmonary tuberculosis group numbered 196; children under 14 made up about 58.5 per cent of this group. There were 138 patients with fractures and burns, and 135 with infantile paralysis. At the time of the study 85.2 per cent of the patients were known to have been ill more than 3 months, and 2,340 of the total 4,316 were ambulatory. Of the 3,127 chronic and acute

patients occupying beds in the 18 general and special hospitals on the census day, 4.9 per cent had been occupying, for more than 3 months, beds designed and maintained for acute cases.

At the time that the study was ended, 18.2 per cent of the 4,316 patients were still in hospitals; 18.8 per cent were under the care of agencies; 10.8 per cent had died; 46.8 per cent had been discharged; and the location of 5.4 per cent was unknown. Of all the chronic sick cared for by the hospitals for chronic diseases, 17 per cent were reported as full pay patients, 15.8 per cent were paying in part, and 67.2 per cent paid nothing.—Survey of Chronic Disease in Boston, Mass., 1927, *New Eng. J. Med.*, 199: 556–574; 620–632 (Sept. 20, 27), 1928.

Health Conditions in the Soviet Union—According to the census of 1926 the population of the Union of Soviet Socialist Republics was 145,806,624. In the Russian Socialist Federated Soviet Republic, one of the most important units of the Soviet Union, there was in 1925 a birth rate of 47.0 and a death rate of 25.9. This gives a natural increase of 21.1 per cent. In the White Russian Socialist Soviet Republic, another unit, the birth rate was 41.0 and the death rate 18.6, a natural increase of 22.4 per cent. In the Ukranian Socialist Soviet Republic the birth rate was 31.5 and the death rate 13.8. These figures may be compared with a birth rate of 21.4 and a death rate of 11.8 in the U. S. Birth Registration Area. The deaths of infants per 1,000 births numbered 213 in the R. S. F. S. R.; 125 in the White Russian S. S. R.; and 146 in Ukranian S. S. R. Contrasted with these is the infant mortality rate of 72 in the U. S. Birth Registration Area.

In 1925 the U. S. S. R. reported 115.2 cases per 100,000 population for typhoid fever; a case rate of 12.7 for smallpox; 450.2 for measles; 186.8 for scarlet fever; 241.8 for whooping cough; 49.4 for diphtheria; 1,957.3 for epidemic influenza; 838.6 for tuberculosis; and a case rate of 347.3 for syphilis.

No figures are available showing mortality by cause in the entire Soviet Union, but there are figures for the city of Moscow. The death rate in Moscow in 1927 was 13.5 per 1,000 population whereas in New York City it was 11.8. Moscow had a death rate of 40.8 for measles in 1927 and New York had a rate of only 0.6. There was a death rate of 19.6 from epidemic influenza in Moscow and 10.6 in New York. The rate for tuberculosis was 157.1 in Moscow, and 86.1 in New York. The rate for cancer was 101.3 in the former city and 124.9 in the latter, and the death rate from syphilis was also lower in Moscow, being 2.1 as compared with 9.2 in New York City. The death rate from puerperal causes was 27.1 per 10,000 births in Moscow, whereas New York showed the much higher rate of 51.3.—J. V. Deporte, *New York State J. Med.*, 28: 1403 (Dec. 1), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Report of the Committee on the Collection and Disposal of Refuse *—The Committee on the Collection and Disposal of Refuse † has had insufficient time since its appointment to prepare a report of permanent value for the 1928 meeting of the Association and after due deliberation concluded it would render better service by recommending a subject for a report at the 1929 meeting to be transmitted to next year's committee after its appointment.

Several subjects suggested at first were finally believed to have been sufficiently covered in earlier reports or textbooks and others seemed better adapted to presentation in the form of a paper or address. After various interviews and correspondence the committee decided to recommend as a subject for the report by next year's committee: "The Collection of Garbage."

Progress Report of the Committee on Water Supplies *—The Committee on Water Supplies † was reorganized such a short time ago that it was impossible to take up some subject and make a report at this meeting. The chairman has been in correspondence with the other members of the committee and we have considered taking up two subjects. One is the relative portions of the burden of pollution which should be assumed by those producing pollution and by the water works or others using the water. The other is bacterial after-growths in water distribution systems. We hope to be able to report on one or both of these problems next year.

Progress Report of the Committee on Sewage Disposal *—The chairman was given to understand soon after the meeting last year in Cincinnati that not much would be expected of the committee † this year. Two brief papers, however, are offered, one by Frank Bachmann entitled "Observations on pH Control of Separate Sludge Digestion Tanks," and the second, by Harrison P. Eddy, entitled "An Account of Legal Action Brought against a Municipality for the Discharge of Filtered Sewage into a Small and Otherwise Unpolluted Stream."

The committee has been asked to suggest a line of work for next year's committee and, in compliance therewith, reports as follows:

During September and October, 1928, suggestions have been received from all the members of the committee. An informal vote upon these suggestions has resulted in a majority favoring for first choice: "The Disposal and Utilization of Sludge," and for second choice: "The Preparation of Standard Forms for the Reporting of Statistical and Operating Data."

One of the suggestions was received too late to take it up further with the committee. I am therefore submitting the above as it stands for the assistance of next year's committee.

Progress Report of Committee on Mosquito Control *—Several changes in the personnel of the Committee on Mosquito Control † were made during the past summer, and the committee did not have the opportunity to organize and conduct any investigations as a

* Presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

† Committee chairmen will welcome suggestions from members of the Section or the Association.

basis for a report at this meeting. The committee has adopted a program for 1929, which embraces the investigation of the phases of mosquito control set forth below and, subject to the approval of the Council, proposes to present, through the medium of a committee report and a special paper by someone qualified to discuss the subject selected for that purpose, those phases which have been satisfactorily developed at that time.

1. Effective and economic oil mixtures and larvicides
2. Improved practical control methods such as the use of mechanical equipment for ditch cutting and maintenance, applying oil and larvicides, etc.
3. Use of repelling agents for protection against mosquitoes on the wing
4. Publicity programs for arousing much needed individual activity in the control of breeding on private property and securing favorable action of legislative and appropriating bodies
5. Essential public health and economic values of general mosquito control
6. Variations in life habits of mosquitoes as they affect practical control

The following brief statement of the considerations which have prompted the selection of the program are given in amplification of the foregoing summary.

It is the general opinion of many experienced workers that oils now available for mosquito control purposes are not of uniform efficiency; that considerable money and time are frequently wasted on this phase of control due to the lack of knowledge of the effectiveness of oils and oil mixtures with their varying degrees of spreading properties, surface tension, toxicity, etc.; and that a product of certain selected specifications should be adopted. Much experimental work along this line has been done in New Jersey during the past year.

New methods develop from time to time. The use of mechanical equipment in several branches of control work has increased in the last two or three years. Where applicable, such equipment in its several forms is a decided economy and is worthy of study.

Knowledge of the effect of repelling agents upon mosquitoes, in the use of which freedom from attack may be obtained, would appear to be of great economic importance. The benefits of absolute protection from mosquitoes, the breeding of which for any reason is not controlled, would be immeasurable in disease prevention. Much progress has been made recently in this line of research, but no definite practice has as yet been established.

In the matter of publicity and education of the public the committee will endeavor to select or develop programs which may change indifference or hostility to active interest and support and which will demonstrate that the attitude of the public in favor of mosquito control demands that a full measure of protection be provided for by legislative and appropriating bodies.

The fifth item is linked up with the preceding one. The sixth is held to offer some practical possibilities.

Airplanes and Paris Green in Control of Anopheles Production—A description is given of the spread of Paris green by airplanes at Quantico and Chopawamsic Bays, Va. Four charts illustrate the decline throughout the summer of the production of adult anopheles in the treated localities and compare such production with that of a controlled, non-treated locality of Aquia Bay. For use in airplane dusting a dilution of 33 per cent of Paris green in powdered soapstone proved most satisfactory for all conditions. In calm weather an excellent distribution of dust was obtained at a height of 150 to 200 feet above the water. The dust penetrated all types of vegetation indigenous on the Atlantic coast.

Suitable intervals between dustings varied with the season: at Quantico they ranged from 6 to 13 days. The ma-

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Catarrhal Prophylaxis in Industry—The published results taken as a whole do not bear out the advertised claims of the manufacturers and venders of stock vaccines. The author tested anticatarrhal vaccines of proprietary manufacture on 79 persons, half of whom were factory staff and half clerical staff, controlled by a corresponding number of persons under exactly similar conditions of employment. In the experimental group 51 per cent developed acute coryza and only 25 per cent in the control group. There was evidence to show that those in the inoculated group were more susceptible to colds. "It would seem to follow, therefore, that the method of giving 3 inoculations at weekly intervals may actually increase the incidence of epidemic coryza," but longer intervals might decrease the same. While better results might obtain from autogenous vaccines, such are not prepared on a large scale and have limited use.—N. Howard Mummery (England), *J. Indust. Hyg.*, X, 9: 295 (Nov.), 1928.

Spray Painters in Automobile Refinishing—Author's conclusions:

Distinct physical defects attributable to benzol are very evident from this study. Of 24 men examined, 7, or 29.1 per cent, showed a blood picture of abnormally low leukocyte count; this finding was not confined to the men directly exposed to the spray. Abnormally high leukocyte count, high red blood cell count, and decreased hemoglobin percentage were also in evidence. In 5 workers, or 20.8 per cent, the spleen was palpable—a surprising percentage and a condition not before clinically reported in such an investigation. Pallor was common, though in some cases with high red counts the complexion was ruddy. Chronic bronchitis, phthisical appearance, and nasopharyngeal irritations were also in evidence. Physical appearance, length of exposure, and the presence or absence of subjective complaints are not indicative of the presence or absence of blood or physical changes or of their severity. Sprayers immediately exposed to sprays or those indirectly exposed may be affected. The blood picture and physical condition before entering this trade must always be kept in mind.

Among other things the author recommends thorough physical examinations and blood examinations every 3 months, with the exclusion of those with anemia or leukopenia, tuberculosis, chronic bronchitis, asthma, myocardial and valvular disease, nephritis or blood dyscrasia. These measures should include those even indirectly exposed. Spraying mixtures should be chemically examined for the presence of benzol. Efficient ventilation must obtain and rooms should be enclosed.—Jerome Meyers (New York City), *J. Indust. Hyg.*, X, 9: 305 (Nov.), 1928.

Some Queries about Respiratory Disease in Industry—More than half the lost time in industry is caused by respiratory disease. A brief study in the Edison Electric Illuminating Company of Boston, for the years 1915 to 1924, showed that 70 per cent of the respiratory diseases were colds and other diseases of the nasal fossae. Community studies show that this condition is not peculiar to industry but the disability varies enormously from plant to plant. The death rate from pneumonia in Akron, O., during 11 years was only 138, while in Youngstown, only 53 miles away, it was 268. The cause is evidently some unknown non-industrial factor. A number of questions arise

such as variations in the medical service supplied, the preventive health features in force, the higher temperatures or change of temperature in certain trades, such as the steel industry, etc. From studies in the cotton weaving industry, variations in humidity would not seem to be a factor, but these workers are afflicted above the average, while woolen workers in similar processes without heat and humidity exposures are afflicted below the average. In some processes the cotton workers have three times the respiratory rates prevailing in others. The study of various trades shows that the worst respiratory mortality is among those subjected to silica dust, less notably those exposed to other dust, those exposed to heat and temperature changes, and, least notably, those exposed to weather conditions. These same trades have the worst mortality from "all causes," including other diseases such as the circulatory group, digestive system, and the kidneys. It would seem that (1) hot moist processes are not nearly so productive of respiratory mortality as dusty trades; (2) pneumonia is especially bad in furnacemen, those in dusty processes, stevedores, and dock laborers. Findings of iron foundry workers by the Metropolitan Life Insurance Company are similar. For the most part the organic dusts are not so harmful as the inorganic.—R. M. Hutton (Canada), *J. Indust. Hyg.*, X, 9: 297, 1928.

Phosphorus Necrosis in the Manufacture of Fireworks—The use of the dangerous white (yellow) phosphorus without due precautions as shown in various fireworks plants in the country has enabled the author to collect the medical histories of 14 cases, descriptions of several of which are given with photographs showing the deformities present. In the three chief plants 366 persons were employed, 181 men and 185 women. Two of the 14 cases were fatal. The manufacturers themselves were experimenting for a less dangerous substitute and one advocated the prohibition in the industry of white phosphorus. Finally the resolution commending the efforts of the U. S. Department of Labor was passed January 30, 1926, by the U. S. Fireworks Manufacturers' Association agreeing to eliminate white phosphorus from the fireworks industry, the same to take effect on or before August 15, 1926. It is expected that cases of this affliction will now be eliminated. New York State is working on a code prohibiting the use of phosphorus fireworks.—Emma France Ward (Baltimore), *J. Indust. Hyg.*, X, 9: 314 (Nov.), 1928.

A Plan of Medical Service for the Industrial Worker and His Family * —The author outlines an elaborate plan undertaken by the Endicott-Johnson Corporation in the three towns in which its plants are located for lessening the disproportion between wages and the cost of medical care. The average annual wage of 30,000,000 industrial workers in the United States in 1925 was $1,250, not enough to provide for adequate medical service. The ideal plant must provide organized medical service and social service of considerable complexity and experience. It should not be arbitrary or compulsory, but competent. It must be flexible.

The Endicott-Johnson plan has been in operation and has proved practical for 15,000 workers in shoe factories and tanneries where the average annual wage is $1,441. There are 28 full-time physicians, 3 full-time dentists, 1 half-time dentist, 5 dental hygienists, 67 full-time trained nurses, 4 pharmacists, 2 bacteriologists, 2 laboratory technicians, 2 physical therapeutists, 1 roentgenologist, 6 motor ambulances, 16 clerks and

* Abstract of paper read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy-Ninth Annual Session of the American Medical Association, Minneapolis, June 13, 1928.

20 other helpers; and, as occasion requires, specialists, nurses, and hospital arrangements. The service is offered to all workers and their dependents, the potential number being about 60,000 persons. The entire expense is borne by the company. "Increased individual production, and profits as the result of this plan, cover the cost."

Preventive medicine is offered in correct feeding, formation of health habits, and the use of vaccines and serums. A rest home in the country is maintained for debilitated girls and women, and a tuberculosis sanatorium at Saranac Lake, N. Y. A workers' sick relief association has 12,000 members and pays a weekly benefit of $10.50, supported with premiums of 20 cents a week. Accident hazards are kept at a minimum by careful supervision. There are no characteristic industrial hazards. Cost of the operating plan for 1927 totals $1,076,809, of which salaries amounted to $301,001, medical bills $193,480, outside service $294,586, and relief $287,742. At the rate of 2.5 cents for each of the 32,000,000 pairs of shoes manufactured by these workers the cost of their medical care can be covered.

DISCUSSION

Dr. T. R. Crowder (Chicago)—What are the difficulties that arise as obstructions on the part of the community and the local physician? Is this an economic procedure? The employe should pay at least a part of the cost. We need a study of the causes and sources of so much illness more than we need curative care.

Dr. V. S. Cheney (Chicago)—We are trying to do too much in industrial work. Other physicians must be considered. The employe should be made to look after himself. His health is what he is selling to the industry.

Dr. S. W. Welch (Montgomery, Ala.)—It is not any part of public health activities to treat the sick. Every man ought to be stimulated to take care of himself.

Dr. E. F. Cody (New Bedford, Mass.)—Has not this company had embarrassing labor difficulties?

Dr. George H. Bigelow (Boston)—This company is doing away with waste, including the waste from disease. It apparently finds it profitable to spend more than $1,000,000 per annum in this direction. It is not a question whether this system recognizes adequately the dignified position of the health officer or the dignified position of the medical practitioner; such is not disturbing the directors of the Endicott-Johnson Corporation.

Dr. W. C. Woodward (Chicago)—A knowledge should be at hand of the terms on which the medical and nursing staffs are employed; of the wages paid to employes in comparison to similar establishments; whether food, fuel and clothing are bought in bulk and issued to employes, and if not, why not, if medical service is furnished. This must be reviewed as a practical social problem. We should be told whether this is also profitable to employes and to the community.

Dr. Louis I. Harris (New York)—It is a question whether the worker is getting all the wages that he is entitled to. Under a system of medical care such as the one outlined, there is not the slightest danger of pauperization when the average wage is only a little more than $1,400 among 15,000 employes. Still are they getting an adequate wage? The plan is one of the varied experimental efforts to compensate for the lack of an adequate system of general medical service, because thus far a statesmanlike approach has not been made to this community problem. The questions should be dealt with in a socially minded way.

Dr. Daniel C. O'Neil—I expected the announcing of this plan here to start something. The worker whose average

wage is only $1,200 for the maintenance of a family is practically pauperized. Our scheme is not compulsory and a limited number of our workers do not avail themselves of the service, and they are not discriminated against. Our average wage below the rank of foreman last year was $1,441. The average wage paid to workers in the shoe industry in general in 1925 was $950.00. We do not furnish food, fuel, rent, and clothing in a wholesale manner, but only to those who suffer misfortune and need such assistance. Likewise our medical service is only for those who need it and who ask for it. Reference is made to the vital statistics of our communities which are in the office of the New York State Department of Health. I recall that our birth rate is nearly double that for upstate New York. Our relations to local physicians and the community are satisfactory and mutually helpful. Medical charity is lifted from them. Opportunity to receive postgraduate instruction is provided.—Daniel C. O'Neil (Binghamton, N. Y.), *J. A. M. A.*, 91, 20: 1516 (Nov. 17), 1928.

Near Vision and Illumination in Industry—Defective products should be charged to (1) raw materials, (2) mechanical factors, and (3) the human factor. Secretary Hoover's Committee on the Elimination of Waste in Industry reported large loss when the eyes are not given proper care. The most vital factor in this is light. The Travellers Insurance Company reports that 24 per cent of 9,100 accidents were caused directly or indirectly by improper lighting. More than 50 per cent of our population suffer from defective vision. More than 25,000,000 are involved in industry. We have found that 18.7 per cent of workers between 22 and 60 years have defective near vision. Eye fatigue can be practically eliminated by proper lighting and correction of refractive errors in the eyes. The efficiency of the individual is increased when 20 minutes rest time is allotted, and the quality of the work may be increased as high as 100 per cent. Our present analysis covers 16,000 employes and the accompanying charts are self-explanatory. Ten to 12 foot candles of light are thought to be the best illumination for close work. Corrected vision and illumination decrease accidents. Lighting should be free from glare and have enough intensity to produce the greatest visual acuity without fear of eye strain, and with short rest periods.—In the discussion, Dr. A. L. Brown said that poor illumination produces muscular imbalance (of the eyes) and is probably responsible for more distress than errors of refraction. Intensity of illumination should vary with the color of the material worked upon, white reflecting from 50 to 70 per cent of light and black only from 2 to 5 per cent.—P. A. Davis, *Ohio State M. J.* (Nov.), 1928, 6 pp.

Legislation on Occupational Diseases in Bolivia—The law passed April 18, 1928, covers (among other needs) various poisons and pathological conditions such as pneumonoconiosis, anthracosis, hydrocarburism, tobacco poisoning, pulmonary sclerosis, nephritis, and pulmonary tuberculosis, which are considered as occupational diseases. Compensation is paid (1) when the disease is contracted in the exercise of the occupation; (2) when the disease is due to the type of work done by the patient during the year preceding disability; (3) when the worker had not suffered from the disease before employment. Those who are principally exposed to pneumonoconiosis will be entitled to 30 days' annual holiday with full pay.—International Labor Office (abstracted from *Monthly Labor Review*), *U. S. Bur. of Labor Statistics*, 27, 5: 67 (Nov.), 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Investigation of the Anti-Bacterial Resistance of Rats with Experimental Rickets—References are given of the observations of previous workers as to the lessening of the resistance toward infection in the case of vitamin deficiency. This investigation was undertaken for the purpose of measuring as specifically as possible the actual degree of resistance to known infection in the case of rats with experimental rickets. The rats, 30 to 35 days old, were placed on the McCollum 3143 diet, slightly modified by the authors, for 5 to 7 weeks. The diet was sufficient in vitamin A and the lack of balance between the calcium and phosphorus was made up by adding monocalcium phosphate in measured amounts. The infection was a strain of *B. suipestifer* introduced by intraperitoneal injection. The minimum lethal dose of this organism was determined both on normal rats and on those with experimental rickets, in the first case being between 22 and 24 million germs and in the latter about 3 million per gram of body weight. The authors showed at the outset that cod liver oil and irradiated sesame oil added to the rachitic diet increased the bacterial resistance. As controls, rats were used on the McCollum diet alone, on a rachitic diet with sesame oil irradiated, and finally normally fed rats. The sesame oil was irradiated by the Bach "Höhensonne" in a layer 1 mm. thick with the lamp at a distance of 30 cm. A number of tables are given showing the results with the different additions to the diet in varying percentages and in combination. The various experiments afford the conclusion that the anti-bacterial resistance of white, normal growing rats toward *B. suipestifer* is 7 to 8 times greater than the resistance of rats of the same age which have been made rachitic by the McCollum diet. The resistance of the rats with experimental rickets can be raised three to fourfold by the addition to the rachitic diet of 3 per cent sesame oil irradiated an hour with the "Höhensonne," or by the addition of 3 per cent cod liver oil. With the addition of 6 per cent sesame oil irradiated for an hour, or 3 per cent irradiated 3 hours, a further increase of the anti-bacterial resistance is not achieved. The anti-bacterial resistance is not increased or cannot be detected when the phosphate deficit in the diet is restored, by irradiation of the rachitic rats with the "Höhensonne," or by a fast of four days' duration. By irradiation normally nourished, growing rats do not show any increase in anti-bacterial resistance compared to normal rats of the same age not irradiated.—Dr. E. Maurer and Dr. P. Hofmann, *Arch. f. Hyg.*, 100, Band 8. Heft, 1928, p. 25.

The Presence of Arsenic in the Fish Organism—In arsenic poisoning the greatest amounts of arsenic are found in the liver and the kidney. In the ordinary articles of the diet, only fish contain arsenic in sufficient amounts to be definitely determined. The Swedish Arsenic Commission found the cod contained from 4.1 to 0.5 mg. of arsenic per kg. of body weight and the herring 0.4 to 0.8 mg. The authors sought to determine whether in the case of fish the arsenic is present in greater amounts in the liver than in the muscle tissue as is the case in human poisoning. In two

experiments on the cod, there was present in the liver 0.7 and 3.2 mg. arsenic per kg. and in the kidney 0.4 and 0.8 mg. per kg., indicating the preponderance in the liver. To determine whether the arsenic exists in the fish or the oil of the fish, raw cod liver was analyzed as well as the alcoholic extracts. Cod liver oil yielded 3.9 mg. per kg. of arsenic and the alcoholic extract contained 44 mg. per kg., the fatty acids of the alcoholic extract 250 mg. per kg. and the alcoholic extract of the residue after vacuum distillation of the fatty acid yielded 1,000 mg. per kg. The muscle tissue of the eel exclusive of certain organs was examined but arsenic was found in such minimal amounts as to warrant no definite conclusion. The muscle tissue of the herring yielded 2 mg. per kg. of the arsenic and the material of the ether extract 9 mg. per kg. The conclusion is reached that the arsenic is normally present in the fat soluble combinations. These are soluble in the usual fat soluble media but with difficulty soluble in water. The concentration of arsenic is greater in the liver of fish than in the muscle tissue. Also the arsenic is present in the oil separated from the muscle tissue and obviously in greater concentration in the extracted oil than in the tissue residue. It may be ascribed to the dissimilar composition of the food of these fish. A discussion is given as to the probability of the combination of the arsenic in the organism of poisoned mammals. According to Heffter there are three hypotheses, the lecithin hypothesis in which arsenious acid is supposed to substitute the phosphoric acid of lecithin; the nuclein hypothesis in which arsenic in a corresponding fashion is supposed to substitute the phosphorus of nucleic acid, and the keratin hypothesis which derives its name from the fact that arsenic is partially eliminated by the nails and hair. Comparison of the records of the presence of arsenic in the case of poisoned mammals and its presence in fish as found in these experiments has led to the conclusion that in the two classes the relationships are dissimilar.—Erik Sadolin, *Biochem. Ztschr.*, 201, Band (Nov.), 1928, p. 323.

Vegetable Food as a Source of Iodine—The very close correlation between the distribution of iodine and the existence of goiter in the United States has prompted a study of some of the vegetable foods in South Carolina, which is practically free from goiter. Investigations so far conducted on vegetables grown in this state indicate that they contain enormous amounts of iodine. Fellenberg reports the amount of iodine necessary to maintain equilibrium in a man is 14 micrograms. Some of the South Carolina potatoes contain enough iodine in a single four-ounce potato to furnish the 14 micrograms. The leafy vegetables are also rich in iodine, beet tops and lettuce running as high as one thousand parts per billion.—Roe E. Remington, *Science*, 68: 590 (Dec. 14), 1928.

Protein and Vitamin B—Reports of investigators as to the varying tolerances of experimental animals to high protein diets suggest that the unfavorable effect observed by some is not due to that factor alone but to the deficiency of some factor or lack of balance. The relation between protein and vitamin B is suggested. Experiments were conducted with rats on a basal diet of edestin, potato starch, butter, salt mixture and distilled water, with no restrictions on the amount of food and water consumed. Rats were weighed daily for the first 4 weeks and afterwards 5 days a week. Experiments are recorded in which this basal diet was supplemented with varying amounts of marmite and growth curves are given both for the experimental rats and those in which the protein was caseinogen or egg-albumin. The results show that the

20 per cent edestin diet with the 5 per cent yeast extract per 100 gm. solid was responsible for the death of many young rats with kidney symptoms but that the older rats were not affected. The symptoms can be prevented by the addition of more yeast extract and the protective factor in this extract is not destroyed by autoclaving at 120° for 4½ to 5 hours. Somewhat less yeast extract is necessary when caseinogen or egg-albumin is substituted. It is suggested that the different proteins may require varying amounts of vitamin B in order to secure proper metabolism.—Gladys Annie Hartwell, *Biochem. J.*, 22: 1212, 1928.

The Effect of the Cow's Ration on the Vitamin A and Vitamin B Content of Milk—Comparisons were made from milk of cows on both a high and a low protein ration. The high protein ration had a nutritive value of 1 : 2 and the low protein ration a nutritive ratio of 1 : 13. To determine the vitamin A content, young albino rats were fed on a vitamin A deficient diet until loss of weight occurred and the diet was then supplemented with milk from each of the groups of cows. Two c.c. of milk caused the resumption of growth in each case and 8 c.c. restored excellent growth. Vitamin B was tested similarly on rats and it was found that 15 c.c. of milk from normal cows and 16 c.c. from high protein cows and 18 c.c. from low protein cows permitted uninterrupted growth over an 8-week period. While the differences are small, the conclusion is reached that the milk from low protein cows contains less vitamin B than that from either the high protein or normal cows. While some recent experimental work has indicated that the presence of vitamin B in milk is not dependent upon the ration but is manufactured in the cow's paunch, the author concludes that this activity is influenced by the feed consumed and this may explain the difference in vitamin B content in this test. It is apparent, however, that a cow can tolerate a very low level of protein feeding without materially affecting the vitamin A and vitamin B of the milk.—W. E. Krauss, *Ohio Agri. Exper. Sta. Bull.*, No. 135 (Nov.–Dec.), 1928, p. 198.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

MATERNAL AND INFANT MORTALITY*

JULIUS LEVY, M. D., FELLOW A. P. H. A.

Bureau of Child Hygiene, State Department of Health, Trenton, N. J.

I. INFANT MORTALITY

MORTALITY UNDER ONE MONTH IN PRINCIPAL COUNTRIES

When charted several interesting features are indicated. In the first place, we see that the neonatal mortality varies considerably among the great countries of the world. This fact in itself is probably the most important fact to be brought out, for if it varies considerably, we are justified in believing that it is in our power to influence and to some extent control the neonatal mortality.

The United States with a neonatal mortality rate of 37.8, while not among the countries with the very highest neonatal mortalities, is to be found, however, among the upper third highest neonatal mortality rates. Attention is called to the low rate reported for Netherlands, 23.6. Similar rates are reported for New Zealand, Irish Free State, Australia, Denmark, and Belgium, all of which present neonatal mortality rates below 30. The rate for the United States is more than 50 per cent higher than that for Netherlands.

Another factor may be emphasized that we hope the committee will be able to clarify. The country with the lowest neonatal rate appears to be Egypt. From our general knowledge of conditions in Egypt, we are not disposed to believe this rate to be correct, and yet it must be included in this report, as it is based upon the official available statistics. We hope in the next report to be able to point out whether this fact is a true one and one to be used in comparison with the other countries.

I might mention here that when we come to discuss the maternal mortality we will find that the same countries which present a low neonatal mortality present a low maternal mortality. Apparently those factors which make for a high maternal mortality at the same time make for a high neonatal mortality. I would immediately make the deduction that any attempt to reduce neonatal mortality will have to deal with the problem of obstetrical care.

TREND OF INFANT MORTALITY

There has been practically no reduction in the mortality under 1 day since 1918. As a matter of fact, statistically there has been a slight rise.

When we take the mortality under 1 month for the same period, we find a percentage fall per year of 1.6, which is a very slight decrease. The reduction in the infant mortality under 1 year has really occurred in the period between 1 month and 12 months, a percentage fall per year of 5.7.

* Abstract of Report of the Committee to Report on the Status of Maternal and Infant Mortality, presented at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association and the American Child Health Association at Chicago, Ill., October 16, 1928.

Again, the fact is emphasized that the methods which have been found effective in reducing infant mortality apparently have had and will have very little effect upon the *early* infant mortality. Now, as it appears that the mortality in the first month of life, and particularly the first week of life, is a large proportion of the total mortality in the first year, it will become clear that any hope of further reducing infant mortality must be found in the efforts that will be directed to this early period.

INFANT MORTALITY BY MONTHS OF AGE IN THE FIRST YEAR OF LIFE

Here is shown the importance of the mortality in the first month. We see that the mortality in the first month, which is 37.9, practically equals the mortality of the succeeding 11 months.

AGE FACTOR IN INFANT MORTALITY

Half of the deaths of the first year occur in the first month, and half of the deaths of the first month occur in the first day, and half of the deaths in the first day occur in the first 3 hours. Therefore, it is very clear that no method of distributing modified milk, establishing mothers' classes, and visiting new-born babies can have a very marked effect upon this mortality, as it is obviously bound up with the obstetrical problem.

INFANT MORTALITY BY HOURS OF THE FIRST DAY OF LIFE

It is clearly evident that if we are going to reduce further infant mortality, we must reach the causes that are effective in the first 24 hours, for in this period one-half of all the deaths under 1 month occur and practically 15 per cent of the deaths under 1 year.

In passing, I would mention that there has been a recent tendency to separate prenatal work from general child hygiene and the infant mortality problem. I believe those who feel responsible for infant life must deal with the prenatal and obstetrical problem.

FIRST DAY'S MORTALITY BY TYPE OF ATTENDANT AT DELIVERY

We find that the mortality in the first day for babies delivered in hospitals was three times as great as for those delivered at home; that the mortality for infants delivered by internes was twice as high as for those delivered by private physicians in hospitals; that among babies delivered at home the mortality for those delivered by physicians was almost twice as high as for those delivered by midwives; that for the entire group the mortality for those delivered at home by midwives was 5.6, while for those delivered in hospitals it was 21.8. Immediately these data present several questions for further study.

Is this high mortality among infants delivered by physicians, and particularly those delivered in hospitals, a coincidence or is there a definite relationship? Is the lower mortality found among infants delivered by midwives and in the home determined by the type of case and the type of woman who comes into the hands of the midwife, or is it due to the greater patience exercised by the midwife? Does the mortality among infants in the first day vary considerably according to the order of pregnancy? What conditions may be obtaining in hospital practice that would explain this very high mortality?

CHANGE IN SEASONAL INCIDENCE OF INFANT MORTALITY

Here we find that in the period, 1913–1914, a very high peak of mortality appears in July and August. When we contrast with this the mortality in 1926–1927 we find not only a complete disappearance of this peak, but a valley, so that it would appear an infant is safer in the summer months now than in the winter months.

RESPIRATORY DISEASES VERSUS DIARRHEA AND ENTERITIS IN INFANTS

We are able to point out that the great reduction of the summer mortality in the past decade is due to a lessening of summer diarrhea. In 1915–1916, summer diarrhea represented 23.5 per cent of the total deaths under 1 year, while in 1925–1926 it represented only 13.7 per cent. As diarrhea occupies a less important place in the mortality of the first year, the respiratory diseases rise in importance but only to a very slight degree. Recalling what has been said about the neonatal mortality, it becomes clear that the mortality of the first year is now mainly due to the diseases associated with the neonatal period.

II. MATERNAL MORTALITY

DEATHS PER 1,000 LIVE BIRTHS

A study of maternal mortality throughout the world shows that the United States presents the second highest mortality for all puerperal conditions and the fourth highest for puerperal sepsis. In contrast with the rate of the United States, which is 6.7 for all puerperal conditions, we would call attention to Netherlands, Norway, Sweden, and Italy, which present rates below 3 per 1,000 live births.

PUERPERAL SEPSIS MORTALITY

There is some encouragement to be found, however, in the study of maternal mortality, in the fact that for a considerable number of states there has been some decline in the past decade in the maternal mortality due to puerperal sepsis. Connecticut, New Hampshire, Vermont, and the District of Columbia have shown an increase.

It is particularly interesting to point out that this reduction of puerperal sepsis has been found also among the colored in Virginia, Maryland, North Carolina, and Kentucky with, however, an increase in the District of Columbia.

IS MATERNAL MORTALITY DECLINING?

We find that the maternal mortality, while showing a decline from 1917 to 1921, has practically remained constant for the past 4 years. Studied by special diseases, we find that there has been a percentage fall per year of 1.4 for puerperal albuminuria and convulsions for the past decade, and a percentage fall of 1.3 per year for puerperal sepsis.

There has been no decline in the past five or six years in maternal deaths from other causes and in one or two there seems to be an increase. Accidents of labor, which are definitely associated with obstetrical care, show a fall for the first 4 years of the decade but practically no fall since 1921. The same is true for accidents of pregnancy and all the other puerperal conditions with the exception of albuminuria and sepsis.

These facts again, when combined with the high mortality found in the first days of life, must direct attention to the question of obstetrical practice. Has there been an increase in the application of forceps, in the use of general anesthesia, in the administration of pituitrin, in general operative interference? May not these tendencies of modern life be the cause of our failure to obtain a reduction in the maternal mortality and in the neonatal mortality, and may not these practices offset the greater attention and care which is being given to the expectant mother or to the woman in the hospital?

PERCENTAGE OF SPECIFIED CONDITION IN TOTAL PUERPERAL MORTALITY

The facts are very clearly brought out when we see that contrasting 1926 with 1917 shows a reduction in puerperal sepsis, a very slight reduction in puerperal albuminuria and convulsions, and an actual increase in the accidents of pregnancy, the accidents of labor, and other puerperal conditions.

PUERPERAL MORTALITY IN URBAN AND RURAL AREAS OF NEW YORK STATE

The puerperal sepsis rate in the urban sections of New York State was more than twice as great as that in the rural sections and there was practically twice as high a mortality in all the other conditions in the urban area as in the rural.

A very interesting fact, too, is that when we consider the percentage fall per year in the death rate for this same period we find that in the urban area there was a percentage fall per year of 0.9 for puerperal sepsis with practically five times as great a fall for the rural area. For all other puerperal conditions the percentage fall has been very similar for urban and rural areas. These data are of particular importance because for purposes of this study the rural area included only communities with populations under 2,500.

PERCENTAGE BIRTHS DELIVERED IN HOSPITALS AND BY MIDWIVES

An attempt was made to study the relationship of hospitalization to maternal and early neonatal mortality. We find that in Minneapolis in 1914, 23 per cent, and in 1927, 78 per cent of the women were delivered in hospitals. This fact is generally looked upon as an evidence of real progress in the care of mothers and a practice that should lead to a marked reduction in maternal and neonatal mortality. However, there has been no reduction in the deaths in the first day of life throughout this period, there has been no reduction in deaths from puerperal sepsis, and there actually has been an increase in deaths from injury at birth. Some 12 cities were examined in regard to similar data and similar information has been obtained.

In Newark, N. J., a very similar situation is indicated. We have been able to include the percentage of women delivered by midwives, and we find that during the period the percentage of women delivered in hospitals has increased from 12 per cent to 50 per cent, and the percentage of women delivered by midwives has decreased from 50 per cent to 23 per cent. The deaths associated with puerperal sepsis have practically been constant. The deaths in the first day of life have shown a slight increase and the deaths associated with injury at birth, which, also, have shown a slight increase, present curves practically identical with those for Minneapolis.

We believe that it is very important to present these facts, so that they may stimulate further study and analysis. Some have intimated that the reason for not obtaining a reduction in puerperal sepsis in those cities which show a high percentage of hospitalization is that the better results obtained in the hospitals with full term deliveries are offset by the great increase in sepsis associated with criminal abortion. We believe that this should be thoroughly investigated to find out if it is an adequate explanation for the rather disappointing results. I think, however, that we are justified in saying that these facts must give pause to anyone offering general hospitalization as a solution to the maternal mortality problem.

NOTE: It will be recalled that at the Annual Meeting of the American Public Health Association in 1927, following a paper by Lee K. Frankel, Ph.D., on the Present Status of Maternal Mortality in the United States, a committee of the Child Hygiene Section of the Association was appointed to carry on studies on maternal and infant mortality. The paper abstracted here, largely in the words of its author, Julius Levy, M.D., chairman of the committee, is the first report of the above mentioned committee.

A more complete report accompanied by some of Dr. Levy's charts will be found in the *Transactions of the American Child Health Association for 1928*.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

The Passing of Miss Maxwell—Numbered among the pioneers of the nursing profession was Anna C. Maxwell. Her pioneer spirit was repeatedly manifested to her associates during a career of usefulness and interest. Miss Maxwell had characteristics which marked her as a unique and unusual personality. She was well known and well beloved.

In recognition of her services during the Spanish-American and World Wars, Miss Maxwell was given the honor of full military burial in Arlington National Cemetery on January 7.

Instruction on Ventilation—Over and over we have heard that sleeping with windows open is imperative. But we know that fresh air is needed all of the time. The new science of air hygiene now teaches a new technic in ventilation. The first requisite of fresh air is that it be of moderate temperature, so as to keep the surface of the body comfortably cool. [The author does not explain how this can be accomplished in summer.] The health temperature is 68° F. or a little below. The second requisite is gentle motion of the air without drafts. A moderate humidity is likewise essential.

In cool, moving air, the body feels comfortable and stimulated. Overheating prevents the most efficient functioning of mind and body. Colds occur more frequently in persons living in overheated apartments. The temperature should never rise above 68° F., except for old people and invalids.

Sleeping rooms should be much cooler than other rooms, but it is not necessary to maintain an outdoor temperature in bedrooms in winter by sleeping with all of the windows open. "If the sleeping room is unheated and the night is very cold, there will be, without much, if any, window opening, sufficient leakage of air around the windows to provide freshness, unless several persons are sleeping in the room." On the other hand, it may be possible to sleep in a room with the windows open and still not have a sufficient supply of air, because the bed may be so far from the window. Usually in climates where the temperature does not go below zero, some opening of the windows is necessary.

The proper place for emphasis in consideration of the new air hygiene is on coolness of air rather than on open windows, as such.—Thomas D. Wood, M.D., and Ethel M. Hendriksen, What the Clinic Should Teach about Ventilation, *Am. J. Nurs.*, 28, 9: 890 (Sept.), 1928. B. J. B.

The Newton Bill (H. R. 14070)—This bill makes provision for the continuance on a national scale of the work now carried on under the Sheppard-Towner Act (Terminates June, 1929). It provides for federal coöperation with states in reducing maternity and infancy death rates, and does *not* demand that state funds be appropriated to match federal funds.

An advisory committee to the chief of the U. S. Children's Bureau is created. Five non-governmental members may be appointed—experts in child welfare and child health—one a health officer appointed from the membership of the Conference of State and Provincial Health Officers.

An Uncompleted Gift—In memory of the nearly 300 American nurses who died during the World War, their compatriots in the same profession contributed $51,000 to house the Florence Nightingale School of Nursing at Bordeaux, France. It was planned to have a central building with two wings. The cost of construction increased so much, however, that it was necessary to omit the erection of one wing. It stands today incomplete. But it is not so to remain. The House of Delegates of the American Nurses' Association at the meeting in Louisville, Ky., in June, 1928, voted that $25,000 should be raised to build the necessary wing. The campaign for the funds, conducted through the state associations, began November 1, and will be officially terminated before the International Council of Nurses meeting in Montreal, Can., in July, 1929, when it is hoped that the amount can be given to a representative of the Bordeaux school.—Virginia McCormick, A Gift is to be Completed, *Am. J. Nurs.*, 28, 12: 1221 (Dec.), 1928.

Health Survey of New Haven, Conn.—The recent study of New Haven's health resources, accomplishments and needs, which was conducted by C.-E. A. Winslow, Dr.P.H., during the past year, is outstanding partly for its completeness and partly for the reason that it follows another study made 10 years ago by the same expert appraiser; and it has all the advantages of perspective and appreciation of obstacles overcome and progress made.

It is now revealed that more than three-fourths of the specific recommendations made in 1917 have already been carried out. A few of the remaining are no longer applicable under changed conditions, and others are under consideration. Such a record of accomplishment, together with the request for this second check-up of community needs before going on, indicates an unusually active and forward-looking attitude toward health which motivates the work of the different health groups in New Haven. The result is, in the opinion of Dr. Winslow, that New Haven promises soon to have the most perfect community health machinery in proportion to its size in the United States.

The survey covers all phases of the community health program, including dispensary and hospital service, visiting nurse service, tuberculosis, school and child welfare nursing, industrial hygiene, social hygiene, health education, sewage disposal, water and milk supply, housing, etc. In the special field of public health nursing, the study was made by Gertrude E. Hodgman, R.N., Yale School of Nursing, and Katharine Tucker, R.N., General Director of the Visiting Nurse Society of Philadelphia. Michael M. Davis, Ph.D., conducted the survey of hospitals and dispensaries. Recommendations for social hygiene were made by William F. Snow, M.D., General Director of the American Social Hygiene Association.

Dr. Winslow summarizes the general ideal toward which efforts in health work should be directed as

> . . . the development of the Health Department as the center for all directive and supervisory health functions; the Visiting Nurse Association as the center of all home nursing service (aside from such functions as communicable disease control); and the New Haven Dispensary as the center of outpatient clinic service (other than conferences for normal mothers and babies).

Specific steps to be taken to lead toward this goal are suggested.

1. The transfer from the Visiting Nurse Association to the Health Department of all responsibility for appointments of conference physicians.
2. The coördination of home service of the Visiting Nurse Association and the Health Department through the transfer of the duties of the present Board of Health Welfare Nurses to the nurses of the Visiting Nurse Association, just

as tuberculosis work has already been transferred. Provision of an annual grant from the Board of Health to the Visiting Nurse Association for maintenance of this work is recommended.

3. The development of venereal disease clinic service in conjunction with the New Haven Dispensary polyclinic service; appropriate financial contribution to be made by the Board of Health for that service.
4. The extension of the services of the Crippled Children's Aid Society so as to be available for patients of all orthopedic physicians.
5. Closer coöperation between the Visiting Nurse Association and the nurses of the Queen's Daughters, so that the latter may give more individual service to chronic and convalescent patients and the acutely ill may be transferred to the visiting nurses.
6. The development of a Council of Community Nursing under the leadership of the Visiting Nurse Association for the purpose of promoting sound growth in the future.

Certain additional expenditures of money are recommended to the Community Chest for the improvement of health facilities, among them being the development of a social service department in the New Haven Hospital and Dispensary, a mental health supervisor for the Visiting Nurse Association, additional nurses to meet increase in population, establishment of a cancer clinic, consideration of some provision for occupational therapy and facilities for the hospitalization of chronic and convalescent patients.

It is the opinion of the author that future developments in health work through the Health Department can be wisely carried out only with adequate financial provision, and a substantial increase in the appropriation for this department is recommended. The transfer of the Division of Vital Statistics to the Department of Health is urged, whereby detailed studies of morbidity conditions may be carried on. Expansion of the Health Department work should be made to provide more thorough school examinations, more comprehensive venereal disease educational and curative work, more popular health instruction and further assistance to relieve the Health Officer of routine inspections.

Haven Emerson, M.D., in a brief comment in the November 15 *Survey*, speaks of Dr. Winslow's survey as "New Haven's health examination" and describes it as the most complete, enlightening and constructive study that has yet been made for any city of its size.—C.-E. A. Winslow, Dr.P.H., *Health Survey of New Haven, 1928.*

K. E. P.

Intracranial Hemorrhage of the New-born—Throughout the length and breadth of the land, health workers are viewing with satisfaction the gradual and appreciable decline in the infant mortality rate during the first year. Dr. Benjamin P. Burpee's paper in the *American Journal of Nursing* forces upon the attention of public health nurses the fact that there is need for more and more watchfulness and keen observation on their part if the death rate among infants in the first month of life is to be lowered still further. To quote Dr. Burpee,

> The most fertile field for lowering the infant death rate under 1 year, at the present time, lies in the reduction of deaths that occur in the first week of life from the condition known as intracranial hemorrhage.

Intracranial hemorrhage is the cause of nearly half the deaths of babies under 2 weeks, and 100,000 babies under 1 month die each year in the United States. Hemorrhage within the cranial cavity is more readily recognized than it used to be, and better diagnosis reveals it as a more frequent complication than was formerly supposed. Early recognition and proper treatment play important rôles in curing the condition and preventing the sequelae.

According to Dr. Burpee, the public health nurse need not be either a practitioner or a diagnostician in order to

recognize the condition immediately so that it may be reported to the attending physician. Intracranial hemorrhage differs from hemorrhagic disease. In the latter, there is a definite increase in both the bleeding and coagulation times. Transfusion should be done both to aid the clotting and bleeding times of the infant's blood and to replace the blood that has been lost by external bleeding. In cases of intracranial hemorrhage only the coagulation increasing elements of the blood are needed. Hemorrhagic disease should be thought of as an entity and as one of the predisposing factors toward intracranial hemorrhage; the other two are asphyxia and trauma.

PREDISPOSING FACTORS WHICH PRODUCE HEMORRHAGE

Trauma—This is probably the greatest single factor; it is the actual laceration of some of the blood vessels within the cranium, resulting in the extravasation of blood somewhere within the brain substance, on the surface of the brain, or within the ventricles. The death rate from intracranial hemorrhage is higher in the first-born and higher in males which average a larger size.

Prematurity—When the blood vessels are not fully developed, they are more easily ruptured.

Syphilis—This is important only in so far as it tends to cause prematurity.

Maternal Toxemia—This tends to make the fetal blood vessels more easily ruptured.

Asphyxia or Congestion and lastly *Hemorrhagic Disease* of the new-born.

ETIOLOGY

Too little is known about the etiology of intracranial hemorrhage, but it is not always due to poor obstetrics since many cases occur in easy, normal, spontaneous deliveries. Trauma is the chief cause although it is often beyond the control of the physician. The use of forceps properly applied does little damage. It is questionable whether pituitrin can cause the hemorrhages by causing too rapid passage of the head through the cervix. It is also logical to suppose that a toxin circulating in the blood of the mother may make the fetal blood vessels more friable.

Some authorities contend that cases of intracranial hemorrhage are infectious and indeed have rather convincing evidence to substantiate their arguments. It is believed that anesthesia plays an unimportant rôle, if any, in the causation of the disease. Obstetricians agree that it is unwise to deliver the fetal head and leave the body in utero since the difference in the two pressures causes an asphyxia and thus may tend to produce hemorrhage. Breech presentation occasionally causes hemorrhage and in combination with prematurity is particularly dangerous. Precipitate labor figures largely because of the rapidity with which the fetal head is pushed through a not completely dilated cervix.

SYMPTOMATOLOGY

Every nurse should familiarize herself with the symptoms of intracranial hemorrhage. The symptoms are not always the same, but there are certain ones which are readily recognizable.

1. *Cessation of normal nursing*—This is the most important single symptom. A new-born infant who is nursing well for the first two or three days and then cannot be made to nurse should be subjected to careful medical inspection.

2. *General attitude of child*—It may be either very restless and crying all the time with a shrill cry suggestive of meningitis if the hemorrhage is on the hemispheres, or it may be very limp and not cry or open its eyes if the hemorrhage is below the tentorium.

3. *Color*—The infant may be pale or cyanotic, again according to the location of the hemorrhage.

4. *Pulse*—The pulse may be either

rapid or slow, from exhaustion or irritation of the vagus nucleus.

5. *Temperature*—This frequently varies from between 103° and 104° to normal or subnormal. Probably the high temperature denotes dehydration.

6. *Respiration*—Difficulty with respiration is a frequent symptom and may even be fatal due to pressure on the respiratory center.

7. *"Continual complaint" or restlessness.*

8. *Cerebral irritation*—This is manifested by twitching of the hands and feet, dysphagia and even convulsions.

9. *Paralysis*—Usually this is a last symptom.

Vomiting and hemorrhages in other parts of the body are other symptoms.

TREATMENT

This consists of two procedures; 20 c.c. of whole blood should be given intramuscularly in varying doses until the symptoms subside. This is a perfectly safe and simple procedure.

Lumbar puncture is performed for the purpose of relieving the pressure within the head. It is the pressure, resulting from the hemorrhage, which causes death. The puncture should be performed every 8, 12, or 24 hours.

SEQUELAE

If the hemorrhage is severe, death takes place rapidly. If the infant survives without having had proper treatment, Little's disease, spastic paralysis, idiocy or feeblemindedness may result in later years, as well as certain types of epilepsy. The early recognition of cases cannot be stressed too greatly.—Benjamin P. Burpee, M.D., Intracranial Hemorrhage of the New-born, *Am. J. Nurs.*, 28, 12: 1183 (Dec.), 1928.

Correspondence Course in Public Health Nursing—A correspondence course in public health nursing given by the University and Bellevue Hospital Medical College, New York, N. Y., in coöperation with the New York State Department of Health is enrolling students for the 1929–1930 courses. The course consists of 25 lessons of 10 hours each, and a residence week of study at one of the large medical centers of New York State is required as a part of the course. The first lessons of the course will be ready for distribution to matriculated students March 1.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Health Appeal in Advertising—The battle royal now on between the competing anti-fat advertisers accentuates the whole problem of health education in various forms by commercial firms. December 8, 1928, the *Journal of the A. M. A.* reviewed the situation as to space advertising. The use of posters and other educational printed matter supplied from commercial sources calls for thoughtful, searching discussion in public health journals and conventions.

One-in-two at Chicago—Devoting the two main sessions of the Public Health Education Section to one theme was quite a success. The new subject of program planning was fortunately presented by a group of speakers with a high batting average. Doubtless de-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

tailed reports will appear in the *Journal*. The group of program outlines distributed in mimeographed form will be supplied for 6 cents postage, while the limited supply lasts. Address the editor. The complete file of year-round programs submitted in advance to the chairman of the two meetings, Mrs. Routzahn, will be loaned for payment of express charges both ways. They weigh 6 pounds. Address the editor.

When the Devil Tempts the Writer—

Commenting on Bunyan's *Pilgrim's Progress*, his biographer states, "The style of the book is plain, such as the lowliest readers—even the farmers that spell out the words—can understand." Bunyan himself says concerning this book, "I could also have stepped into a style much higher than this in which I have here discoursed, and could have adorned all things more than here I have seemed to do; but I dare not. God did not play in convincing of me; the Devil did not play in tempting of me; wherefore I may not play in my relating of them, but be plain and simple, and lay down the thing as it was. He that liketh it, let him receive it; and he that does not, let him produce a better."

The celebration of the 300th anniversary of the birth of Bunyan this year and the fact that his *Pilgrim's Progress* is said to be the most popular book in the English language with the exception of the Bible, gives this advice special significance. Personally, I love his recipe for writing. Now for the first time I know that whenever I put an especially elaborate literary flourish into a manuscript, it is the Devil that has tempted me.

—Louise Franklin Bache, National Probation Assn.

Health in 1929 Commencements—

The emphasis on health as the special theme of the 1929 commencements should (a) lead each graduate to adopt a high standard of fitness for himself and to understand how to maintain that standard in terms of personal habits and medical and dental care; (b) include a special study by each graduating class of the time lost in its own school as a result of ill health, the findings to be presented as a part of a commencement program; (c) include special study of the lives of such great torchbearers for health as Pasteur, Walter Reed, and William Osler; (d) include awards of school letters to graduates who have maintained high standards of health and school coöperation; (e) include special consideration by classes in professional colleges of education, medicine, law, and engineering of the part each profession can take in the improvement of public health.—

A Movement to Vitalize Commencements, *Journal of National Education Assn.*, Washington, Dec., 1928.

In the January issue the *Journal* urges again that health and safety be emphasized in 1929 commencements, and offers specific suggestions for elementary schools, junior high schools, senior high schools, colleges and professional schools. In colleges "orations and essays may be built around the lives of pioneers who have made significant contributions to medicine or public health. These may be descriptions of recent great discoveries such as insulin." In professional schools "let law students show how health may be advanced through better legislation," and so on. 25 cents for copy, 50 cents for both issues.

Doubts from the Outside—

In the absence of any definite proof of the nature of influenza, the present rush to close schools is of doubtful value. Children may easily find in the hours away from school exposures and risks that are quite as serious as those of the classroom. For millions of city people the common injunction to stay away from crowds is ludicrous in its impossibility of fulfilment. We live, move, and snuffle in crowds whether we will or not—and in the subways of New York we breathe in our neighbors' faces with undisturbed serenity because there is no other place to breathe.

—*The Nation*, Jan. 2, 1929.

Two Opportunities not to be Missed—The Early Diagnosis Campaign of the tuberculosis associations in March, and National Negro Health Week, March 31 to April 7, 1929, both offer possibilities for all health agencies and coöperating groups—not to help out the sponsoring organizations, but to utilize the opportunities presented. Ad-

dress any tuberculosis association and National Negro Health Week, Tuskegee Institute, Ala. At a conference of Negro Health Week leaders " it seemed to be the consensus of opinion that one of the greatest needs is an adequate supply of well trained public health nurses."

" Enter Your Tb Publicity Relics " —This is the plea of Dr. H. E. Kleinschmidt, as a committee of the National Tuberculosis Association. The specimens from a " dim, dark past " of tuberculosis publicity and education will be exhibited at the National Tuberculosis Association's 25th anniversary meeting at Atlantic City, N. J., in May.

Have We Listed the Leading Citizens?—Mrs. Mary Breckinridge, director of the Frontier Nursing Service in Kentucky, is reported as saying:

> The leading citizens of any community comprise approximately 10 per cent of its population. If the nurse seeks these out, uses them in committees and gets them educated as to what she is trying to do, she can accomplish anything.

Who are the " leading citizens "? The key individuals? The key organizations in the city or county? Have we made a plan, covering a year or several years, to inform them and to enlist them?

CONTESTS

In the April 1, 1929, poster contest conducted by the Massachusetts S. P. C. A. medals with blue ribbons are offered for first prizes, and medals with red ribbons for second prizes, with honorable mention for every school entering the contest. A good idea for health poster contests?

The Massachusetts contest covers drawings by pencil, or crayon, pen and ink, cut-out paper (original, not magazine covers, etc.), or silhouette, water color or charcoal. The use of colors is strongly recommended. For full conditions as a sample write the society, at 180 Longwood Ave., Boston, Mass.

A New York city worker asks about essay or limerick contests. Please send details of your contests, or mention who have held such contests.

If you have made use of soap sculpture, you will wish to get details of the fifth annual competition for prizes—closing May 1. Address: National Small Soap Sculpture Committee, 80 East 11th St., New York, N. Y.

Another simplified description of " Cutting and Printing Linoleum Blocks " is in *Scouting*, 2 Park Ave., New York, N. Y., Nov., 1928. 10 cents. Linoleum blocks offer possibilities for a new line of illustration for printed matter, and as a contest among children or adults.

The aftermath of the New York State Diphtheria Poster Contest is notable for the well developed plans for getting the most out of what might have been merely a contest in poster designing, with awards and a public display of the winning posters. Now that the first prize poster has been reproduced as a 24-sheet billboard poster the use planning continues. The winning artist will unveil one of the posters on LaFayette Square, in the center of downtown Buffalo. In many cities the schools will participate in the local " unveiling." Mrs. Marie F. Kirwan, S. C. A. A., 105 East 22d St., New York, N. Y., will send copies of mimeographed bulletins regarding the uses made of the poster contest. (One reader of this copy raises a question: Is the unveiling idea over-emphasis? What do you say?)

EXHIBITS

A blue ribbon was awarded the State Fair exhibit of the Tennessee State Dept. of Health. Entitled the " Journey through Life," " the periods of life —prenatal, maternal, infancy, preschool, school, adolescence, adult and old age

—were depicted by cardboard cut-out illustrations which showed both the correct and incorrect methods of living."

For those who visit New York City: the American Museum of Safety is at 120 East 28th Street, east of 4th Avenue. Leave any subway at 28th Street and go to the east.

How portable window exhibits were made by the staff of Bellevue-Yorkville Health Demonstration, New York, N. Y., and how drug-stores were led to give window space, is told in "Selling Health in Drug-stores," by Marjorie D. Candee, *Survey*, Jan. 15, 1929.

Many of the gay holiday wrapping papers (including those sold in five and ten cent stores) will give life to dull health posters and placards. Mount the poster so that several inches of the wrapper show on the top and both sides —and an inch or two more at the bottom.

The Smithsonian Institute, Washington, D. C., has issued a booklet descriptive of its permanent exhibit of visual lessons in health and hygiene and "those matters concerning personal and community cleanliness which should be known everywhere." 25 cents.

When you wish to construct a miniature bathroom as an exhibit, ask Jane Hufford, Chicago Tuberculosis Institute, 360 North Michigan Blvd., Chicago, Ill., for a copy of typewritten description. Miss Hufford reports that Marshall Field and Co., Chicago, sell for 95 cents a set of white enameled metal bathroom furniture. Bedroom furniture sells for $1.95—in white or mahogany.

MEETINGS

Five regional meetings of public health nurses in Indiana "were very successful." The groups were so small and informal that everyone felt free to bring up her problems and express her ideas.

How about trying on your service or luncheon clubs the idea of once a year calling for a "grand jury" report on the health problems of club members—the "jury" being appointed by a club a month or two in advance of the luncheon where the report will be presented? A new approach for getting group consideration of personal or community health needs?

IS PUBLICITY NEEDED?

The hygiene teacher in a mid-western college took her class to the headquarters of the local Visiting Nurse Association. Afterwards, one of the young men said, "I'm so glad we made that visit. I'd often seen those visiting nurses on the street, but I always thought they were nuns."

Any further examples to go under this heading?

WORDS

"A bath every day keeps you fit in every way."—In house organ of a state department of health. (Can this be true? Will their readers believe it to be true? If not, then what?)

RADIO

In the Public Health Section of the British Medical Assn. Dr. W. W. Jameson strongly commended "frequent four-minute broadcasts on matters of special health interest" as being more effective than longer talks at monthly intervals.—*The Lancet*, Aug. 18, 1928.

Recently, the Union des Grandes Associations Francaises pour l'Essor National (Union of French Associations for National Development) organized a special wireless health propaganda week. . . . Eminent French specialists spoke on school hygiene, housing, the venereal diseases, the anti-tuberculosis campaign, mental hygiene, health and education, the campaign against cancer, social insurance, women and public health, child welfare, and the anti-alcohol campaign.—*The World's Health*.

Feb., 1928. How like a "health week" program west of the Atlantic!—most everything, but not much of anything.

Two radio talks on cancer appeared in the July, 1928, issue of *Campaign Notes,* Am. Soc. for the Control of Cancer, 25 West 43d St., New York, N. Y.

Ten stations are now broadcasting a series of talks supervised by the Canadian Social Hygiene Council. Talks on child hygiene, smallpox, diphtheria, etc., are included in the series.

REPORTS

"One of the weak points in the popular health education progress of the city is the lack of standardized annual reports for the various public health agencies which will permit a central agency, such as the Federation or the Health Department, to compile the facts concerning the activities of the agencies, so as to present a composite picture of all activities in a particular field. The bringing together of information for public presentation of the needs in any field and the facilities available for meeting these needs is essential if continued and adequate public support is to be obtained."—*An Appraisal of Public Health Activities in Cincinnati, Ohio, for the Year 1926,* by the Committee on Administrative Practice of the American Public Health Association, p. 99.

A well organized account of widely diversified activities scattered over the whole country is presented in *The Story of May Day: 1924–1928,* by Katherine Glover. 108 pages. American Child Health Assn., 370 Seventh Ave., New York, N. Y. The half tones are grouped on 8 pages of good dull finish paper in the center of the book. Curiously enough there is no publication date. We think there should have been a table of contents or index, or both.

PEOPLE TO KNOW

George A. Dundon is now director of health education, Health Department, Milwaukee, Wis.

Thomas A. Burke has succeeded Arnold A. Mowbray as director of public relations, National Safety Council.

Mary Ross, who handles health topics in *The Survey,* and Bernard C. Roloff, Chicago Department of Health, are members of the Executive Committee of Educational Publicity Division of the National Conference of Social Work. Evart G. Routzahn was elected chairman for 1928–1929.

BOOKS AND REPORTS

Annals of the Pickett-Thompson Research Laboratory (*Vol. IV, Pt. 1*) —*London: Baillière, Tindall & Cox. Baltimore: Williams & Wilkins, Nov., 1928.* 250 pp. Price, $10.00.

The first of the volumes devoted to the streptococci was reviewed in this *Journal* in June, 1928, page 829. The present volume begins the study of the pathogenic streptococci and is given practically entirely to the rôle which these organisms play in rheumatic fever and its complications. Chorea is definitely declared to be a manifestation of cerebral rheumatism, a theory which has been held by some for many years, but has not been definitely accepted. The authors do not venture an opinion as to the etiology of erythema nodosum, though they give evidence indicating that it may be caused by streptococci, point out its apparent contagiousness and its relation to rheumatism, tonsillitis and endocarditis. Approximately 110 pages are given to the study of rheumatic carditis, including some 14 pages on treatment by streptococcal vaccines and sera.

With the exception of the section on erythema nodosum, the authors sum up the literature and give their conclusions. They hold that rheumatic fever is a definite specific disease exhibiting such constant and typical lesions as to make it highly probable that it is caused by a definite specific organism. It is generally preceded or accompanied by sore throat, so that it is probable that the specific organisms enter the system through the tonsils, in which they may remain for a longer or shorter time, causing systemic effects by the absorption of their toxins. They consider it much more probable that the germ enters the system. There is equally good evidence that the streptococci play an extremely important part in the production of rheumatic fever and carditis, but the differentiation of the varieties has been faulty and great confusion has resulted.

The authors continue to follow the methods devised by Dr. Crowe, and hold that the differential medium with the photographs of cultures introduced by him " will constitute a new stimulus and initiate a new era in bacteriological research." This opinion is again expressed in spite of some criticisms of the method after the appearance of Volume III.

The present work, like Volume III, shows an enormous amount of careful study of the literature and collation of facts. The microphotographs are excellent.

Volume IV will be completed by four further monographs, and will be followed by two more volumes on the pathogenic streptococci. In view of the excellence of the two volumes so far issued, we must look forward with much interest to those promised, and it may be again predicted that the entire series will be the most complete and authentic study of the streptococci which has been made. The volumes will be indispensable to every bacteriologist.

M. P. RAVENEL

Protecting the Semi-public Water Supplies along Pennsylvania's Highways—*Pamphlet of Pennsylvania State Health Dept.* 50 pp.

During the early spring and summer an intensive drive was made on semi-public water supplies along Pennsylvania highways. Thirty-two hundred miles of roads were covered and 3,130 drinking water supplies investigated.

Two mobile laboratories and the main state laboratory were used. Nine engineers, 3 laboratory assistants and 3 technicians composed the personnel.

Forty-five pages of the pamphlet are devoted to a detailed record of all supplies examined. It is to be noted that less than 50 per cent of the supplies examined on the first trip around were approved. ARTHUR P. MILLER

Handbook of the Health Exhibits of the United States National Museum—*By Charles Whitebread. Washington, D. C.: Smithsonian Institute, 1928.* 39 pp. Price, $.25.

In 1922 a Hall of Health was established in the Arts and Industries Building of the United States National Museum. This national health and hygiene exhibit has been growing gradually and is now fairly extensive, though not as yet commensurate with its original plan. The exhibit is ably described in this well printed and attractively illustrated pamphlet, which should be of value to all who are interested in public health education. JAMES A. TOBEY

A Doctor Looks at Marriage and Medicine—*By Joseph Collins, M.D. Garden City: Doubleday, Doran, 1928.* 313 pp. Price, $3.00.

Physicians have their own way of looking at things. Unless it be lawyers, none more than physicians have occasion to look into the complicated question of marriage. This title, in passing, is somewhat misleading. It might better have been "A Physician Looks at Marriage and Medicine," because there are many other kinds of doctors—divinity, philosophy, and whatnot.

After reading this book one must resume the attitude of expectancy. We still await *the* book by a physician on marriage as excellent in its presentation as the subject is important.

In the midst of a lot of words there are some arresting thoughts which occur at just sufficiently frequent intervals to keep one reading on. It is not very concise; it is none too clear; and better perhaps for neurologists to wade through, for the mental legs of ordinary readers are too short and not built for quick turns.

Some of the schemes advanced are novel, to say the least. For instance, on page 47 it is advocated that an intelligent woman, whom eugenists would class as a good breeder, should approach one of the opposite kind with the proposal that she will raise so many more children if the poor stock person will agree to breed so many less. Does the author advocate that plan seriously, or with his tongue in his cheek, or like a boy with a stone who throws it through a window to hear the glass crash?

The author assumes an attitude something like this: Now I shall stand apart as a neutral and discuss a very perplexing question. But, he does not maintain that attitude, for his neutrality is constantly interrupted by personal opinions which he occasionally seeks to bolster up with statistics. Where statistics are not available, or not sufficiently forceful, guesses are substituted in their place. W. W. PETER

The Principles and Practice of the Dilution Method of Sewage Disposal—*By W. E. Adeney. New York: Macmillan, 1928.* 161 pp. Price, $5.00.

Considering the fact that over three-quarters of the population of the United States disposes of its sewage by dilution in water courses, it is surprising that the dilution method of disposal has not been the subject of a fairly comprehensive text. This lack the present volume supplies in a very satisfactory and helpful manner. Once more, but in this instance in more detailed fashion, the general principle is emphasized that discharge of sewage into a stream, in con-

trolled amounts, offers a true method of disposal, comparable in status with, and more widespread in application than any other method of disposal now available. The indiscriminate prohibition of discharge of raw or settled sewage into streams, at present the gospel of some misguided sportsmen, is as unintelligent a program of action as a policy of unrestricted discharge would be. Dr. Adeney sets forth in unusually instructive fashion the general principles underlying the dilution method of disposal and the analytical indices of purification helpful in the application of these principles. He supplies a reference book of much importance to those concerned with the significant problems of sewage disposal. Lay and professional readers will be impressed with the interesting and logical evolution of the subject matter, from both the historical and scientific viewpoints.

The author is peculiarly fitted for the present task by virtue of his own original contributions to research in sewage disposal and his affiliation with the investigations of the Royal Commission on Sewage Disposal of England, the Metropolitan Sewerage Commission of New York, the Sanitary District of Chicago, and of similar agencies elsewhere. His theme is that any given river has a measurable capacity, through the agencies naturally existing in it, for the work of disposing of and purifying the raw or settled sewage of a community, at the same time protecting properly the amenities of the river and its fish and vegetable life. The recognition of this principle is of vast economic and sanitary importance.

In the development of the theme, the author points out the fundamental fallacy, originally given authoritative emphasis by the erroneous conclusions of the Rivers Pollution Commission of 1868, that the changes in a sewage polluted river were purely chemical rather than biochemical in nature. Finding no traces in their studies of streams of characteristic end-products of complete oxidation, the commission's recommendations resulted in the unscientific and unsuccessful prohibitive legislation, the Rivers Pollution Prevention Act of 1876. In intent and in theory, the Act returned streams to their pristine purity; in fact, it did little more than retard progress in stream pollution investigation and regimentation.

Adeney reviews the progress from that time on and provides a remarkably clear analysis of the historical and scientific data now available in this field. Chapters are devoted to characteristics of bacteria and higher forms of stream life, the course of fermentative changes of sewage matter, the formation and effects of "humus," the mechanism of purification of sewage liquor by the dilution method, the rates of consumption of dissolved oxygen by sewage and the rate and mechanism of surface aeration. A chapter is devoted to a careful comparison of the standards earlier recommended by the Royal Commission with the area and depths of streams.

It is gratifying to note the author's emphasis, in Chapter 8, upon the injurious effects of sewage solids in rivers and streams, an emphasis entirely concordant with the experience and policy of most American engineers.

The book concludes with several chapters on methods of analysis, special apparatus, and collection of samples. The bibliography is excellent, the table of contents most complete and instructive, and the paper, typography and arrangement attest the usual high standard of the productions of the Cambridge University Press.

The reviewer cannot resist the temptation to inquire, at no risk of reflecting upon the excellence of the present text, why the author refers so briefly and, we may presume, inadequately to the excellent contributions on the mechanism of stream purification issued

by the Cincinnati Stream Studies Station of the U. S. Public Health Service. Their findings would add even further to the already great value of the text.

ABEL WOLMAN

Fundamental Gymnastics—*By Niels Bukh. Translated, rearranged and adapted for use in America by Emily Russell Andrews and Karen Vesterdal. New York: Dutton, 1928.* 202 pp. Price, $2.00.

This book attempts to set forth the theories and practices in gymnastics of Niels Bukh, whose work in Denmark has considerable vogue, and which has been much advertised and exploited by a certain group in the United States.

Originally it was designed by Bukh to correct maladjustments and faulty occupational habits of posture. In this country, those who have been most interested are largely specialists in the corrective and remedial field of gymnastics.

These gymnastics are designed to remedy stiffness, lack of power, and awkwardness or lack of coördination. The objectives, as set forth in the text, are flexibility, strength, and coördination or agility. The translators claim that the exercises were not designed as a system, and that they are made up of non-definite movements. These aim also to "increased and unlimited range of movement." They are somewhat self-testing.

The book, in addition to general statements and exercises, presents definite chapters on exercises for flexibility, strength, coördination, combined exercises, and self-testing exercises.

The exercises described are largely of the corrective-gymnastic type, frequently reënforced by the individual grasping his own legs or ankles to secure greater flection at the hip and back. Many of them are forced and strained and frequently made more so by the pulling or pushing of a second individual. They tend particularly to pull and stretch the structures of the lower back.

These are formal exercises—many of them of great power—which would be corrective in the hands of an expert, but dangerous in the hands of a person who did not have an intimate knowledge of the anatomical structures concerned, and also an intimate knowledge of kinesiology. These are not exercises to be used by the product of some six weeks' summer course. For the person interested and trained in the corrective gymnastics, this book presents many valuable exercises.

C. H. KEENE

Wheat Flour and Diet—*By C. O. Swanson, Ph.D. New York: Macmillan, 1928.* 203 pp. Price, $2.50.

Although some food faddists and similar fanatics have attempted to decry the plentiful use of bread in the diet, usually for absurd and fantastic reasons, the "staff of life" properly continues to be one of our most important and valuable foodstuffs. By no means is it a complete food, but all competent authorities agree that at least one-quarter of the daily diet may consist of cereal foods, including white bread. Professor Swanson recognizes the limitations as well as the value of wheat and does not hesitate to set forth the former and to recommend that bread be supplemented in the diet with such all-round foods as milk and leafy green vegetables. Most modern bread is, for that matter, made with milk. This book is not propaganda for wheat, but is an impartial and accurate account of the kinds of wheat, their preparation and methods of milling, the food constituents of wheat, and its proper place in the diet. The chapters on nutrition are correct and the whole book will be of value to sanitarians, home economics workers, and others who desire succinct information on this subject. The book should also be of value and interest to the general lay public.

JAMES A. TOBEY

The Genesis of Epidemics and the Natural History of Disease. *An introduction to the science of epidemiology based upon the study of malaria, influenza and plague—By Clifford Allchin Gill, Lt. Col., Indian Medical Service. New York: William Wood.* 550 pp., 19 charts, 10 maps, 1 diagram. 1928. Price, $7.50.

The author's primary and basic thesis is that epidemics of all diseases and all types of epidemics are dependent upon an identical mechanism. The genesis of epidemics is in all probability the outcome of a unitary mechanism. The nature of this mechanism is explained by the quantum theory which postulates that all epidemical phenomena are essentially dependent upon a change in the relationship of the infection quantum and the immunity quantum. It ascribes the precise cause of "loss of equilibrium" between "infection" and "immunity," primarily and predominantly, to an increase of the infection quantum; in other words, it postulates that the essential factor in the causation of epidemics is of a quantitative rather than a qualitative nature. The theory also regards the circumstances associated with oscillation of the infection quantum as likewise conducive to correlated oscillations of the immunity quantum.

An epidemic is thus regarded as mainly the outcome of a quantitative change of the transmission factor and the immunity factor, and the intensity of epidemics is held to be a function of the range of amplitude of these factors, which, in turn, is attributed to the influence of climatic conditions in determining a great and sudden elevation of the infection quantum and a corresponding depression of the immunity quantum.

Other subsidiary factors are concerned in the operation of the quantum theory; thus climatic conditions responsible for the oscillations of the infection quantum and of the immunity quantum may occasion correlated changes of the human factor and of the parasite factor also, which add to the disturbances in the equilibrium between infection and immunity.

It might appear that this admission by the author would allow for changes in virulence in the parasite which he elsewhere seeks to set aside as quantitative rather than qualitative. He regards the occurrence of qualitative changes in specific parasites in the direction of exalted virulence as not entirely free from doubt. Attenuation is not discussed in this connection.

Prolificity, induced by favorable climatic or other conditions, in his opinion affords a quantitative aspect of the toxicity of epidemics, which may be substituted for the qualitative change in the *materies morbi*. It may be held that the difference of toxicity exhibited by pneumonic and bubonic plague is indicative of the variable virulence of the plague bacillus, but it may with equal cogency be argued that the facts are capable of an alternative explanation. It is, in fact, possible that an aerial route of transmission has placed the organism in an environment highly favorable to its prolificity—in other words, to its multiplication—and that the extreme toxicity of pneumonic plague, as compared with bubonic plague, is indicative of an extremely high infection quantum. The relative toxicity of the pulmonary form of anthrax (wool-sorter's disease) and malignant pustule, and of pulmonary tuberculosis, as compared with lupus, may be susceptible of a similar explanation; it is possible therefore that a change of toxicity, in association with a change in the route of transmission, is indicative of a change in the quantum of infection.

In the light of these considerations it

is held that the enhanced toxicity exhibited by epidemics is capable of explanation in terms of a change in the quantum of infection, and that, since the facts appear to be capable of explanation upon this basis, it is unnecessary to assume that the specific parasite undergoes any change of virulence prior to the occurrence of epidemics.

The author has applied his quantum theory to the epidemics of malaria, plague, and influenza in recent years in the Punjab and in every case finds that the data are in conformity with his quantum theory. One of the striking features of the epidemic diseases of India is their higher intensities, measured in the case of a lethal disease, by the death rate per 1,000 of the population, in the subtropical as compared with the tropical parts of that country. Malaria in subtropical India may reach a mortality twenty times above normal. Plague mortality in 1898–1918 was 122.2 in the Punjab, 3.4 in Madras, and 1.4 in Bengal. In the pandemic of influenza of 1918–1919 the death rate in the plains of the Punjab was 58, and only 8.5 per 1,000 in Bengal. It is therefore clear that each of these three great epidemic diseases—two of which are insect borne and one air borne—exhibit precisely similar features in respect of their high intensity in the north and their low intensity in the strictly tropical parts of India. The available data in connection with epidemics of relapsing fever and smallpox (before the introduction of vaccination) are also consistent with the view that these diseases also exhibit relatively high intensity in the north of India, and it is therefore justifiable to conclude that "intensity" constitutes one of the generic features of epidemics, and that it should, in consequence, be explicable in terms of the quantum theory.

The more equable conditions in the tropical parts of the country prevent marked disturbances in the equilibrium between infection and immunity, while the sharp climatic contrasts in the Punjab afford opportunities of great disturbances and thus for epidemics of maximum intensity. The high death rate in the Punjab is the outcome of the influence of climatic conditions upon the unitary infection-immunity mechanism.

"What is it moulds the life of man?
The Weather!"
What is it swings the scythe of Death?
The Weather!

Biologists, not statisticians, are not as yet convinced, however, that genetic differences in host and parasite can be thus dismissed as factors in epidemics. The recent evidence of the experimental induction by Muller and by Patterson of similar changes in germ cells and soma by radiant energy tends to support the view that biological changes in both host and parasite, as well as the weather, may be concerned in the problems of epidemiology. C. A. KOFOID

An Introduction to Practical Bacteriology—*By T. J. Mackie, M.D., D.P.H., and J. E. McCartney, M.D., D.Sc. (2d ed.) New York: William Wood, 1928.* 390 pp. Price, $3.50.

During the 3 years which have elapsed since the appearance of the first edition of this excellent practical guide, bacteriology has made considerable advances. The authors have taken advantage of the necessity for a new edition, not only to bring the material up to date, but also to supply some deficiencies noted in the first edition. The size of the book has been increased by approximately 100 pages. The most notable additions are an increase in the material devoted to immunological methods and brief details concerning the most important pathogenic organisms of domestic animals. Many of these produce disease in man, and others, the streptococci for example, are

identical in appearance in man and animals, and the bacteriologist must know all types in order to conduct his work properly.

The authors speak rather positively about the Dick reaction, and do not give the Dochez method of producing antitoxin. They do not mention either the vaccine or serum against anthrax. General methods for the preparation of bacterial vaccines are given, but these do not apply to anthrax vaccine.

On the whole, we consider the work among the best of its type, and can heartily recommend it to teachers and students alike. The printing and binding are good. The price seems excessive for a book of its size.

M. P. RAVENEL

The Community Use of Schools—*By Eleanor Touroff Glueck. Baltimore: Williams & Wilkins, 1927.* 222 pp. Price, $3.00.

In an interesting and well written volume Dr. Glueck presents the results of her study of the extra-curricular use of school buildings in the United States. Her personal contact with the school center movement in Boston covering a number of years makes her discussion of the problems involved in this movement especially significant. She has in this study attempted to secure, for the first time, with the assistance of the U. S. Bureau of Education, information regarding the school center movement in rural sections of the country.

Dr. Glueck, for the purpose of this study, has defined a social center as the use of a school building once a week for two types of activity, or twice a week for one type not including night schools. She reports a more general use of school buildings for community purposes in rural districts than in cities. While but 5½ per cent are being used regularly for community purposes, the school houses in the United States are quite generally open for occasional community purposes. The administration of school centers is usually under the board of education, but 10 per cent of centers are under the control of private groups, though 21 per cent are entirely self supporting.

A valuable part of the book is a compilation of the school laws of the various states which have to do with the use of school buildings for community purposes. In a chapter tracing the development of interest in the use of school buildings for outside activities, Dr. Glueck points out the various factors which have influenced state legislation on this subject. The states are shown to vary in regard to this aspect of schools fully as much as they do in regard to other phases of education. Oregon has a state law prohibiting dancing in public schools. Some states prohibit religious meetings, others permit them. Dr. Glueck feels that interchange of experience among those interested in the movement is one of the greatest needs of the present day. Creative leadership such as the movement in Wisconsin has had, would go far to assist in solving some of the problems in connection with the administration and conduct of school centers.

JOSEPHINE BROWN

A Manual of Water Supply, Sewerage and Sewage Treatment for Public Buildings in Ohio, *for Engineers, Architects, etc. Div. of San. Engineering, State Department of Health, Columbus, O., 1928.* 13 pp. and charts.

This excellent bulletin defines for designers the requirements of the state health department with respect to water supply and sewage treatment devices for such buildings as are not situated so as to have access to public water and sewerage systems.

Applicable sections of Ohio laws are quoted, and suitable cuts of wells and sewage treatment appliances are shown.

It is pointed out, however, that the cuts are not intended to be working drawings but to illustrate essential details.

Architects and engineers engaged in designing public schools and other buildings in Ohio should welcome this publication, as it leaves no doubt nor makes no mystery of what is desired. Consistent use of it should tend to improve and standardize sanitary installations in that state. ARTHUR P. MILLER

Progress Report on Cannery Waste Treatment Studies. *State Department of Health of Ohio, 1928.* 85 pp.

This bulletin presents in a concise form the results of researches on the treatment of cannery wastes.

During the fall of 1926, at Canal Winchester, O., the Ohio Canners Association fostered studies of the treatment of raw wastes from packing plants for corn, succotash and lima beans by means of fine mesh mechanical screens, chemical precipitation, and chlorine sterilization, and of the oxidizing of these wastes screened on coarse filters of laths and of crushed limestone as well as on two sand filters.

During 1927, the Association of New York State Canners, Inc., continued these studies at Albion, N. Y., by investigating principally the oxidation of wastes from green bean and tomato packing plants. Some data on dried bean canning and pea wastes were also procured.

Both studies are admirably summarized at the beginning of the bulletin, making it unnecessary to read the entire mass of data unless a detailed study of it is essential.

The conclusions can probably not be stated better than in the summary where they are given as follows:

1. Mechanically operated fine screens with openings of about 0.010 inch are most essential features of treatment plants. Where oxidizing processes are employed for tomato products waste, following screening a relatively short period of sedimentation is necessary.

2. The organic matters in finely screened corn, lima bean, succotash and green bean wastes are removed with sufficient thoroughness to correspond to the requirements of extremely limited dilution, by coarse grained trickling filters operated at rates of 2,000,000 gals. per acre per day and 250,000 gals. per acre-ft.

3. Coarse grained trickling filters operated at the above rates cause a substantial reduction in the organic matters dissolved in finely screened and settled tomato products waste, but under the test conditions the effluent is not stable, requiring at least a four-fold dilution with normal stream water.

4. Chemical precipitants under controlled application and with effective arrangements for the complete separation of the resulting floc, remove to a most substantial degree the dissolved organic matters in finely screened tomato products waste. The settled effluent is completely stable.

5. Where waste treatment is required, the complete separation of cooling water from the wastes proper is essential.

6. Silage or stack juices should ordinarily be removed by cartage. Similar disposition may often advantageously be made of blancher wastes from pea and dried bean processing. Core-skin puree should be hauled away if produced, or preferably tomato residues incident to chili sauce production should be conveyed to carts uncycloned.

ARTHUR P. MILLER

Lehrbuch der Hygiene für Studierende, Arzte und Gesundheitsbehörden—*By Dr. med. et phil. Ernst Gerhard Dresel. Berlin: Urban & Schwarzenberg, 1928.* 499 pp. 38 figs. Price, $5.50.

The comprehensive nature of hygiene as conceived by the Professor of Hygiene and the Director of the Hygienic Institute of the University of Greifswald is illustrated in this textbook. The guiding principle appears to be development of the physical and social life of man which this science protects from unhygienic modes of life arising from industrial necessities, untoward customs and ignorance. The social art of healthful living in the midst of urban industrial life is the underlying theme. General

theoretical considerations usually conceived as within the field of sociology receive generous consideration, such as movements of population, age at marriage, decline of birth rate, sterility, influences of the industrial age, Taylorismus and Fordismus, and governmental insurance.

The book is an admirable one in its wealth of detail, as, for example, under conditions of health we find discussions in manifold particulars of air, weather and climate, water, soil, clothing, food and nutrition in greatest detail. The personal hygiene of all ages and conditions of men is analyzed especially with reference to the health of the workers in the industries.

The discussion of communicable diseases is far less satisfactory, since it is so abbreviated and condensed.

CHARLES A. KOFOID

Handwörterbuch der Arbeitswissenschaft unter Mitwirkung von 280 Fachleuten des In- und Auslandes —*Herausgegeben von Privatdozent Dr. Fritz Giese.* (*Halle a/S., Carl Marhold Verlagsbuchhandlung.*) *1. Lieferung: Abbau-Arbeitsmedizin.* Columns 1–320 (160 pp.). 1927. Price, RM. 9.00.

This is an ambitious piece of dictionary making which attempts an objective presentation of the data pertaining to labor without favor of concession to nation, party, class or confession. It aims to furnish a systematic, scientific presentation of "Arbeitswissenschaft" in the technical, medical, psychological, legal, pedagogic, industrial, and philosophical aspects. It will be issued in 10 parts, constituting 2 volumes, to be completed early in 1928. The 8-hour day, alcohol, old age relief and old age insurance, worker's psychology, America, and industrial hygiene are among the subjects treated in the first part, and bibliographies are appended to the leading entries. Under "Alkohol" we note an entire omission of American data and no citation of American work. Guinea-pigs, Volstead and abstainers are noteworthy for their absence. The discussion of industrial hygiene contains a useful summary of existing German regulations for the protection of workers from industrial hazards. The work promises to be a valuable summary of current German ideas, custom and practice as regards labor, and therefore very timely for reference and comparison.

CHARLES A. KOFOID

Sanitary Engineering Laboratory Manual—*Arranged by Robert B. Van Horn. Seattle: University of Washington Book Store, 1928.* 23 pp.

This manual, prepared particularly for use in the University of Washington sanitary engineering laboratory, might better be titled so as to indicate application in a water laboratory as it refers only to tests on water.

After brief descriptions of the types of analyses, the sanitary survey, interpretation of results, sampling, and laboratory technic, the author covers laboratory procedures for making physical, bacteriological, microscopic and some chemical examinations. The text is suitable for instruction purposes because of its simplicity and its exclusion of matter not necessary for the use of the beginner.

ARTHUR P. MILLER

The Voyage of Growing Up—*By C. E. Turner and Grace T. Hallock. New York: Heath, 1928.* 192 pp. Price, $.76.

This volume has been prepared for the third and fourth grades and presents health training activities in an interesting manner to children of this school age. A criticism that can be made of this story of the two children who have health adventures is that it attempts to combine mythology, realism and health education. However, the book is charmingly written.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Los Angeles, Calif.—The cover and title page of this report for the year ending June 30, 1928, bear the seal of the city, founded in 1781. An introductory statement of the health officer is that the health department supervises the health of 1,250,000 persons and watches the sanitation of a city of 425 square miles, with a per capita expenditure of 56 cents. Health bureaus have been established in special districts at Venice, San Pedro, Watts, Sawtelle, and Van Nuys, in addition to 23 "health centers" which "provide a personal touch with individual and family units in their own environment."

Following a financial statement are reports of the various divisions. It is noteworthy that the nursing division gives care to the sick in their homes, "at the same time teaching the family the way of healthy living. . . . The expectant mother is taught the principles of personal hygiene, as especially adapted to her needs." The division is now providing nursing care to the policy holders of the John Hancock Mutual Life Insurance Company and the West Coast Life Insurance Company on a fee per visit basis. Good photographs illustrate some of the problems in the nursing field.

Another interesting feature is the account of the city maternity service which received 3,564 applications for care, and supervised 1,334 deliveries. There were 3,540 prenatal calls to patients' homes and 10,513 post partum visits. Attendance at the maternity dispensaries included 3,085 new cases and 9,713 old cases. At this clinic there were 2,611 new cases interviewed by the Social Service Bureau. "We believe that a service which can point to 1,334 deliveries without loss of life to a single mother is a service that is of inestimable value to Los Angeles and to the country as a whole." A group of 8 resident physicians devote their entire time to this work, in addition to a staff of attending obstetricians and consultants.

The object of the dispensaries is to provide medical supervision for those women who are unable to pay for the services of a physician during their pregnancy, regardless of whether they are to be delivered by the service, or expect to go to the General Hospital or to some other similar institution for confinement. Patients are required to go to the dispensary every two weeks throughout pregnancy. A routine Wassermann is done on every new case, and urinalysis and blood pressure readings are taken at each visit. Two social service investigators are employed, but the report recommends that this work be assumed by the Nursing Division under the direction of a social service supervisor.

Seattle, Wash.—Under the title "Your Health Department," the Seattle health and sanitation bulletin, beginning with October, 1927, has carried a series of interesting articles dealing with the health department and health conditions in that city. These articles have been carefully prepared, with headings and sub-headings, charts and photographs, appropriately distributed throughout the series. The activities charted include administration and vital statistics, quarantine, plumbing inspection, milk, meat and dairy inspection, sanitation, laboratories, hospitals and clinics, social service, tuberculosis control, child welfare, garbage collection and disposal, and insect control.

The Commissioner of Health exercises supervision over all health department

activities and is responsible for all policies other than those laid down in the regulations of the State Board of Health or in the ordinances of the city council. The city charter provides that he must be a physician. The commissioner also acts as head of the division of vital statistics, as this "health bookkeeping" is closely related to administration affairs.

Infant mortality rates have declined in this city from 118 in 1905, and 84 in 1910, to 41 in 1927. Three units comprise the child welfare division of the health department, including administration, clinic service and visiting nurse service. The child welfare clinics are primarily for the purpose of keeping well children well. In addition, all the clinical, laboratory, and hospital facilities of the department are available for the purpose of making diagnosis or giving treatment when necessary. The physicians in attendance at the clinics are selected children's specialists. "Some parents fail to bring their infants and children to the clinics. Their children need care and supervision as urgently as those in regular attendance. These children are reached through the efforts of the visiting nurse, who goes to their homes as well as to the homes of those who attend the clinics."

Illinois—The second volume of *The Rise and Fall of Disease in Illinois,* published by the State Department of Public Health in commemoration of its 50th birthday, 1927, is devoted to a history of local health service, and a summary of the work at Chicago and at each of 27 down-state municipalities. Further chapters relate to the sanitary district movement, the tuberculosis sanatorium movement, rural health service, and the sanitary supervision of milk. An appendix contains the annals of health, sanitation, and public health service. It is a well bound volume of 493 pages, and contains a detailed general index as well as an index of auxiliary health agencies, and a bibliography.

The sections of each of the down-state municipalities contain a short history of the public health movement in the city concerned, and a description of the health machinery, water supply, sewerage, and general health conditions. Graphs and tables clearly present the essential vital statistics, and recognition of service is given by picture reproductions of past and present health officers.

The section on Chicago is rendered in greater detail. The health department of the city was established July 19, 1876, taking over the powers and duties of the board of health which had been in existence since 1867. The ordinance provided for a commissioner and an assistant commissioner of health, a secretary and assistant, two meat inspectors and 13 sanitary policemen.

From here the work of the department is reviewed in successive steps, the first being the pre-bacteriologic period, 1876–1892, the first years of which were those of highest death rates, chiefly due to communicable diseases. To combat these, the reporting of contagious diseases by physicians, and the placarding of scarlet fever were made effective in 1877 and diphtheria isolation was started in 1888. However, the more productive work of this period was concerned with the improvement of tenement house and workshop and filth conditions, the surveys leading to the establishment of the Chicago Sanitary District in 1889 and the building of the drainage canal.

The second period, 1892–1906, was that of the control of communicable diseases through applications of the bacteriological principles uncovered by Pasteur and Koch in the 70's and 80's, and the development of food and milk inspection. Dairy inspection was started in 1902, and sanitary inspections of milk depots and bacteriological ex-

aminations of milk samples in 1905. Publicity and education in public health work became recognized as of prime importance, and much attention was given to educational propaganda. The development of quasi-public agencies came in this period, the Chicago Visiting Nurse Association, 1888, Hull House, 1889, Chicago Lying-in Hospital, 1895, Chicago Association of Day Nurseries, 1897, City Club, 1903, and the Juvenile Protective League, 1904. The efforts of the department during the last period, 1907–1927, have been directed toward the systematic control of the various preventable diseases, and the enlargement, on a comprehensive scale, of the other activities of the department, such as the control of the milk supply, meat and food inspection, ventilation, and water supply control.

The sanitary district movement in Illinois, initiated by the establishment of the Chicago district, has grown rapidly in the last few years. In 1911 the creation of the North Shore Sanitary District was authorized, and after the passing of the Act of 1917, which authorized the creation of sanitary districts wherever a desire was manifested by petition, 17 other sanitary districts have been started.

The agitation for tuberculosis control was initiated in the 90's, but proceeded slowly until 1908 when legislation was passed to construct and maintain tuberculosis sanatoriums in cities where desired by popular vote. This led to the gradual growth of the county sanatorium idea which was recognized by legislation in 1915. Since that time 46 counties have been collecting taxes under the tuberculosis sanatorium law, and 15 sanatoriums have been built.

The unfavorable action of the past three legislatures has seriously handicapped efforts toward the establishment of full-time county health officers as the initial step in rural health service. With the aid of the Rockefeller Foundation and the U. S. Public Health Service, however, several full-time county health departments have been organized.

Newark, N. J.—The first page of Newark's 43d report is reproduced because of the information given in a brief space in the introduction.

Newark—A Healthy City

(Population July 1, 1927—467,000)

Outstanding Evidences in 1927	
Crude Death Rate (5,086 deaths) (Lowest ever)	10.9 per 1,000
Adjusted Death Rate (4,837 deaths) (Including Soho & Verona deaths, excluding non-residents)	10.3 per 1,000
Birth Rates (10,042 births) (Lowest ever)	21.5 per 1,000
Infant Mortality (deaths under 1 year per 1,000 living births—lowest ever)	63.3
Typhoid fever mortality	1.3 per 100,000
Tuberculosis mortality (all forms) (Lowest ever)	82.9 per 100,000
Diphtheria mortality	13.3 per 100,000
Scarlet fever mortality	2.6 per 100,000
Smallpox mortality	Not one death since 1903

Among other features, this report has one of the best series of graphs contained in any report during the year. Disease reports are classified by age, sex, month, and wards of the city. A classified financial table concludes the report.

New Haven, Conn.—Bound in gray covers, the report of this city of 184,887 population covers 59 pages. Its attractiveness and readability would be improved by the use of soft paper and larger type for the descriptive text. A good organization chart showing bureaus, personnel, and budget, occupies an introductory page. A resident death rate of 10.0, a birth rate of 19.0, an infant mortality rate of 54.0, a pulmonary tuberculosis rate of 44.3, and a diphtheria rate of 1.6, are reported. There were no deaths from typhoid fever during the year.

Under a new anti-tuberculosis program, with a full-time medical director, nursing service is provided by the Visiting Nurse Association. To assist in the recognition of early cases, the department gives financial assistance for X-ray examinations for patients not in the dispensary group, but for whom the standard charge would be a hardship. An up-to-date register of cases has been prepared. All anti-tuberculosis forces of the community have been coördinated and are working together smoothly and efficiently.

During 1927 nearly 5,000 children were added to the list protected from diphtheria, and of this number 2,000 were babies or in the preschool group. A large proportion of the school group is now protected. Under the auspices of the Health Section of the Community Chest, a comprehensive health survey of the city was undertaken and was completed in 1928. A limited number of copies of the published report is available for distribution to health officers who may desire them.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Causes of Puerperal Septicemia—The report of a Massachusetts Committee to investigate deaths due to puerperal septicemia summarizes the causes. Similar investigations in other states ought to have a wholesome influence on maternal health.

ANON. Report of the Committee on Survey of Incidence of Puerperal Septicemia in Massachusetts, 1927. New England J. Med., 199, 25: 1253 (Dec. 20), 1928.

Frequency of Pfeiffer's Bacillus Findings—Pfeiffer's bacillus, found frequently in normal throats at all times, was more frequently recovered from people with colds, much more frequently in pneumonia. There was no correspondence between the incidence of the bacillus and influenza.

BOURN, J. M. Incidence of Pfeiffer's Bacillus in Throats during Epidemic and Interepidemic Periods in Chicago. J. Prev. Med., 2, 6: 441 (Nov.), 1928.

Milk Sickness—An article describing the metabolic disturbances in animals caused by eating the white snakeroot and the effect upon humans consuming milk from sick cows.

BULGER, H. A., *et al.* Milk Sickness and the Metabolic Disturbances in White Snakeroot Poisoning. J. A. M. A., 91, 25: 1964 (Dec. 22), 1928.

Prohibition—Dr. Emerson shows the decrease in deaths from alcoholism and cirrhosis of the liver, and the decline in the percentage of admissions of alcoholic psychoses to mental hospitals, which point to an improvement in public health brought about by prohibition. In addition, he calls attention to improvements in the general and tuberculosis death rates, the decrease in cases of drug addiction, crimes against chastity, the increase in school attendance in upper grades, and the increase of milk consumption, and offers these as evidence of value of prohibition to public health.

EMERSON, HAVEN. Prohibition and Public Health. Survey, 61, 5: 289 (Dec. 1), 1928.

Experiments in Food Poisoning—Heat-killed cultures of nine strains of *Salmonella sp.* when fed on an empty stomach failed to produce symptoms of food poisoning. This experiment gives no support to the theory that outbreaks of food poisoning have been caused by a thermostable toxin of these organisms.

DACK, G. M., *et al.* Unsuccessful Attempt to Produce Salmonella Intoxication in Man. J. Prev. Med., 2, 6: 479 (Nov.), 1928.

Chlorination of Water—This paper reports upon municipal experience in pre-chlorination of water supplies, the use of chlorin in algae control and in preventing sludge putrefaction.

ENSLOW, L. H. Progress in Chlorination of Water. J. Am. Water Works A., 20, 6: 819 (Dec.), 1928.

Regional Vaccination—A translation of a rather flowery account of Besredka's method of local immunization against staphylococci and streptococci. The paper is intended for the intelligent layman.

EPSTEIN, S. Antivirus Vaccines in Surgery. Scient. Month., Jan., 1929.

Health Examinations and Cancer—Periodic health examinations carefully done will discover precancerous

conditions and the earliest evidences of localized cancer. A plea is made for physicians to "expose" themselves to the contagion of enthusiasm for the health examination project. A valuable antidote for such papers as the recent one by Clendening.

FAUGHT, F. A. Health Examinations as a Means of Diagnosis in Cancer Control. Med. J. & Rec., 128, 10: 515 (Nov. 21), 1928.

Midwifery in Great Britain—A brief account of the prenatal and postnatal services established in England. Interesting as a comparison of the work there and in most states of the U. S. A.

FLIEGER, M. L. Midwifery in Great Britain. Am. J. Nurs., Dec., 1928, p. 1194.

Epidemiology of Whooping Cough—An enlightening review of the subject, showing, among other interesting findings, that whooping cough is the most common of the diseases that frequently cause death in the preschool years, and that 95 per cent of all deaths from whooping cough occur during the first 5 years of life. The protection of young children by isolation and vaccination is urged. The preventive campaign is much the same as for measles.

GODFREY, E. S. Epidemiology of Whooping Cough. New York State J. Med., 28, 23: 1410 (Dec. 1), 1928.

Improving Faulty Posture—A discussion of exercises by which posture defects may be corrected by bringing into proper action the antigravity muscles.

HAYNES, R. S. Postural Reflexes. Am. J. Dis. Child., 36, 6: 1094 (Dec.), 1928.

Cod Liver Oil in Milk—A brief note suggesting the substitution of cod liver oil for some of the fat content of milk used in infant feeding.

IRISH, H. E. Cod Liver Oil as a Substitute for Cream in Feeding Mixtures for Infants. J. A. M. A., 91, 24: 1884 (Dec. 15), 1928.

School Lighting Practice—A summarization of the school lighting requirements of 39 states; includes color of walls, exposure, window-floor ratios, intensity of artificial illumination, glare, etc.

IVES, J. E. A Review of the Current Practice of the Lighting of School Buildings in the United States. Pub. Health Rep., 43, 50: 3313 (Dec. 14), 1928.

Immunization against Scarlet Fever—A summary of the successful results in Michigan institutions in immunizing with scarlatinal streptococcus toxin.

KIEFER, G. L. The Value of Active Immunization against Scarlet Fever. J. A. M. A., 91, 24: 1885 (Dec. 15), 1928.

Antituberculosis Work—Another answer to Fishberg's attack on the policies of the N. T. A. The general principles of tuberculosis prevention are discussed and the fallacies of Fishberg's contentions are demonstrated.

KNOPF, S. A. Forty Years of Antituberculosis Work. Med. J. & Rec., 128, 11: 553 (Dec. 5), 1928.

Milk Borne Streptococcus Infections—An outbreak of unusual gastric disturbances in a school was traced to the consumption of milk from a cow with chronic mastitis.

LAIDLAW, F. W. The Epidemiology of an Outbreak of Illness Due to Milk. New York State J. Med., 28, 24: 1465 (Dec. 15), 1928.

Endemic Typhus Fever—The typhus-like disease, which is endemic in the United States, occurs chiefly along the Eastern Seaboard and Gulf Coast with occasional cases reported from the interior and the Pacific Coast. The greatest concentration of cases is found in the southeastern states, particularly Alabama and Georgia.

MAXCY, K. F. The Distribution of Endemic Typhus (Brill's Disease) in the United States. Pub. Health Rep., 43, 47: 3084 (Nov. 23), 1928.

Rural Health Work—A report of the 109 coöperative rural health projects of the U. S. P. H. S. The total of sanitary improvements effected, health educational projects completed, accomplishments in personal hygiene and correction of physical defects, and cases of communicable diseases cared for, makes a most impressive picture of real accomplishment.

LUMSDEN, L. L. Coöperative Rural Health Work of the Public Health Service in the Fiscal Year 1928. Pub. Health Rep., 43, 48: 3149 (Nov. 30), 1928.

Whooping Cough Prophylaxis—In the authors' experience, vaccine proved of little, if any, value in the prophylaxis of whooping cough. He concludes that early diagnosis and quarantine are the only effective control measures.

SAVER, L. W., and HAMBRECHT, L. Whooping Cough. J. A. M. A., 91, 24: 1861 (Dec. 15), 1928.

Preventing Rickets by Irradiation—In a group of 237 babies artificial ultra-violet irradiation was found a practical method of preventing rickets if begun early and given regularly.

SELKIRK, T. K., *et al.* Studies in Rickets. J. A. M. A., 91, 26: 2057 (Dec. 29), 1928.

Cross Connections—The paper recounts water-borne enteric outbreaks due to pollution through cross connections, acts passed prohibiting cross connections, and concludes that, although with specified check valves properly inspected, the hazard is reduced, the sensible procedure is the eventual elimination of all cross connections.

SHERMAN, C. W. Cross Connections—The Health Hazard vs. the Fire Hazard. J. Am. Water Works A., 20, 5: 615 (Nov.), 1928.

Measles Prophylaxis—The Health Department of the City of Syracuse endeavored to supply measles convalescent serum for use in children under 3 years. The principles governing serum prophylaxis are discussed in detail. It is suggested that the extremely low mortality in the large outbreak may have been, at least in part, due to the use of convalescent serum. Experiments with animal serums failed to yield positive results.

SILVERMAN, A. C. Serum Prophylaxis in a Measles Epidemic. J. A. M. A., 91, 23: 1786 (Dec. 8), 1928.

Measuring Ultra-Violet Light—A simple chemical method is suggested for the quantitative estimation of ultra-violet light in sunshine, which correlates closely with the erythema reaction of the skin. The quantity and quality of the available ultra-violet light in Chicago over a period of 16 months are measured and discussed. A most valuable paper.

TONNEY, F. O., *et al.* Actinic Measurement of Solar Ultra-Violet Light and Some Correlation with the Erythema Dose. J. Prev. Med., 2, 6: 493 (Nov.), 1928.

Problems of Old Age—The proceedings of the Annual Graduate Fortnight of the N. Y. Academy of Medicine—a symposium on the problem of Aging and Old Age—are published in this and the succeeding three issues of the Bulletin. It will constitute a valuable record which ought to be in every health library. The four issues may be purchased for $1.00.

VINCENT, G. E., *et al.* Symposium on the Problem of Aging and of Old Age. Bull. N. Y. Acad. M., 4, 11: 1062 (Nov.), 1928.

Heart Disease Studies—Of 500 children in a heart disease clinic, four-fifths had a rheumatic history, the average age of onset of which was 7 years. After 12 years the tendency to infection diminishes. The severity of the rheumatic manifestations bore no relation to the degree of heart involvement.

WILSON, M. G., *et al.* Statistical Studies Bearing on Problems in the Classification of Heart Disease. Am. Heart J., 4, 2: 164 (Dec.), 1928.

NEWS FROM THE FIELD

GIRLS' COLLEGE IN SANTIAGO

THE board of regents of the University of the State of New York has recently granted a provisional charter to the Santiago, Chile, College for Girls. This school was established in 1880, and was originally devoted to the education of girls from America and England, but was later opened to the daughters of Chilean families, many of whom now attend.

This is the second educational institution in South America chartered by the board of regents, the first being Mackensie College of Sao Paulo, Brazil.

SEWAGE RECLAIMED FOR INDUSTRIAL USE AT GRAND CANYON NATIONAL PARK

AFTER much investigation on the part of the U. S. Public Health Service, a sewage disposal plant has been erected and is now in operation on the south rim of the Grand Canyon. The experiment carried on by the federal agency has proved that it is possible to produce continuously a sewage effluent of the same quality as drinking water in so far as bacteriological results are concerned, and of better quality than the original water for generating steam. Authorities are also convinced that where there is a scarcity of water, particularly in the West and Southwest, it will be economically practicable to reclaim sewage for industrial purposes and for irrigating any kind of crops without danger of contaminating ground water or the products grown. The same degree of purification will not be required for sewage which is used for irrigation as for industrial purposes. However, sterilization will be necessary for reclaimed sewage used in growing vegetables and some other crops.

TEAR GAS USED IN FUMIGATION OF SHIPS

POISONOUS cyanogen products have been successfully tried out by the U. S. Public Health Service in the fumigation of ships arriving from foreign ports. The report recently made by the Service accentuates the advisability of using cyanogen products, which include a sufficient amount of tear gas to serve as a warning agent.

TRAVELING DENTAL CLINICS IN THE ANTIPODES

TRAVELING dental clinics giving service in the rural districts of Victoria and Queensland, Australia, have been instituted. In Victoria free dental service is given to school children until they reach the age of 12 years, and in Queensland the treatment of adults is given for a small fee. The location of the dental van is broadcast every Thursday from the Queensland radio station and the immediate itinerary of it given. The Queensland van covered 3,000 miles in 8 months.

ELEVENTH TEXAS WATER WORKS SHORT SCHOOL

THE Eleventh Annual Texas Water Works Short School was held January 14–22, and the convention of the Texas Section, Southwest Water Works Association, was held immediately following, January 23–25, at the Agricultural and Mechanical College and at Bryan, Tex. The short school was arranged under the auspices of the Texas Section, Southwest Water Works Association, the Agricultural and Mechanical College of Texas, the Texas State Department of Health, the City of Bryan and the Bryan and Brazos County Chamber of Commerce. The

school is planned each year to give the water works man of the small city an opportunity to obtain more knowledge of water and sewage treatment and to help him solve his local problems by the laboratory and lecture courses.

COURSES FOR PUBLIC HEALTH WORKERS OFFERED BY JOHNS HOPKINS UNIVERSITY

A COURSE for public health officers and other qualified persons engaged in public health work will be given at the Johns Hopkins University, School of Hygiene and Public Health, Baltimore, Md., during the third trimester, March 13–June 1. The course will include statistics, epidemiology, sanitary engineering, public health administration, bacteriology, immunology, protozoölogy, entomology, helminthology, physiological hygiene, chemical hygiene and the filterable viruses. Lectures will be supplemented by laboratory exercises and field demonstrations.

Candidates for admission to the course must be graduates in medicine or have had scientific training which will fit them for the course.

TRAGIC DEATH OF DR. SILVER AND WIFE

DR. Horatio Silver, 55, Health Commissioner of Preble County, O., and his wife were shot and killed by burglars in their home at Eaton, O., December 8. The robbers entered the bedroom of the Silvers and as Mrs. Silver rose from her bed she was killed by a bullet through her heart. Dr. Silver was shot in the stomach and died five hours later at a Dayton hospital.

A daughter aged 13 occupying a room across the hall from her parents was awakened by the shots and her screams aroused the neighbors. The murderers escaped and county police authorities have not been able to identify them from the inadequate description of them given by Dr. Silver on his deathbed. The robbers obtained only $10 in cash, taken from Dr. Silver's trousers pockets.

INFLUENZA IN LOS ANGELES

WALTER M. Dickie, M.D., State Health Officer, Berkeley, Calif., reports that Los Angeles County had had 5,182 cases of influenza up to December 1 in the present outbreak, while the total for the state under observation at that time was 8,712. In Los Angeles, 600 new cases were reported December 6, and in the first 6 days of December there were 2,821 cases, among which there had been 70 deaths.

DR. BRISTOL RESIGNS FROM MILBANK MEMORIAL FUND

LEVERETT D. Bristol, M.D., Fellow A. P. H. A., executive officer of the Bellevue-Yorkville Health Demonstration, has resigned to accept a position in the industrial health field. Dr. Bristol has been with the Milbank Memorial Fund Health Demonstrations in New York for 6 years as executive officer.

PERSONALS

DR. EDWARD T. DEVINE has been appointed director of the Bellevue-Yorkville Health Demonstration, New York, N. Y., to fill the vacancy caused by the resignation of Dr. Leverett D. Bristol. The announcement of Dr. Devine's appointment was made by Shirley W. Wynne, M.D., Health Commissioner of New York City. The local health department is using the Bellevue-Yorkville Health Demonstration district as a health labora-

tory to try out public health programs. This demonstration is one of three being financed in part by the Milbank Memorial Fund.

DR. ARTHUR H. GRAHAM, Wetumpka, Ala., head of the Elmore County health unit, has been promoted to the position of District Health Officer of southeastern Alabama, comprising 19 counties, and Dr. Lewis Roy Poole, Dothan, Ala., has become head of the Elmore County health unit.

DR. CHARLES A. DIMOND has been named city physician of Keokuk, Ia., to succeed Dr. William Frank Brown, resigned. Dr. Dimond was formerly city physician for several years.

DR. EDWARD S. GODFREY, JR., director, Division of Communicable Diseases, New York State Department of Health, has been appointed clinical professor of epidemiology of the College of Physicians and Surgeons, Columbia University.

DR. CHARLES A. WATERHOUSE, Health Officer of the Sherman consolidated health district in Chautauqua County, N. Y., since 1919, died December 5 from pneumonia.

DR. ARTHUR T. DAVIS, executive secretary of the Delaware State Board of Health, was recently appointed Health Officer of Suffolk County, Del.

DR. GEORGE H. COOMBS, director, Divisions of Social Hygiene and Communicable Disease, of the Maine State Board of Health, resigned in December to resume private practice in his former home, Waldoboro, Me. Dr. Coombs served with the Maine State Department of Health for 8 years.

DR. A. E. MCCLUE, for some time director of the full-time health unit of Hancock County, W. Va., has resigned to enter private practice. His successor is Dr. James E. Fisher of Ohio, who has done much public health work in Alabama.

DR. MARSHALL C. BALFOUR, who until October served as director of the Field Training Station for the Mississippi flood area at Indianola, Miss., has been assigned to the New York City office of the International Health Division of the Rockefeller Foundation, to succeed Dr. Charles N. Leach, who has been transferred to a European post. Dr. Balfour has had extensive experience in public health work in this country and in Europe. From September, 1926, to July, 1927, he was engaged in malaria investigations in North Carolina.

DR. ABRAHAM J. COHEN, Philadelphia, Pa., has been appointed chief of the Division of Tuberculosis of the Municipal Bureau of Health to succeed the late Dr. Thomas Mellor Tyson. Dr. Cohen has been medical director of the Eagleville (Pa.) Sanatorium for 19 years and has served also as assistant director of the Henry Phipps Institute.

Age Distribution in Milk-Borne Outbreaks of Scarlet Fever and Diphtheria*

EDWARD S. GODFREY, JR., M. D., FELLOW A. P. H. A.

Director, Division of Communicable Disease, State Department of Health, Albany, N. Y.

THAT there has been an unusual proportion of adult cases in milk-borne outbreaks of scarlet fever, seems first to have been noted by Littlejohn in 1899.[1] Ker,[2] in his textbook, gives it not only as a characteristic of scarlet fever but of diphtheria as well. More recently, Clarke[3, 4, 5] has called attention to the phenomenon and suggested its value as a means for the early diagnosis of milk-borne outbreaks.

Strangely enough, although this peculiarity has been noted in the reports of numerous outbreaks, the only allusions to it as a characteristic appear to be those quoted, all of which are from Edinburgh authorities. Ker,[2] indeed, thought this might be merely a local characteristic due primarily to the extensive use of milk on porridge by Scotch adults. Of the 9 diphtheria outbreaks cited by Clarke,[6] however, 5 were in England.

The only allusions to this peculiarity as a characteristic of milk-borne infection that I have found in American literature are in the pamphlet on scarlet fever published by the U. S. Public Health Service in 1914,[6] in an article of my own on outbreaks attributed to pasteurized milk,[7] and in the recent study by Armstrong and Parran.[8] There has not been, so far as I am aware, any inquiry to determine how frequently this peculiarity shows itself nor to account for its occurrence.

With the idea of contributing something toward the answer to the

* Read at a Special Session on Epidemiology of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

first of these questions, I have tabulated by age all of the cases attributed to milk-borne infection with scarlet fever and diphtheria that have occurred in New York State since 1914, and all of those found in recent literature in which the age distribution has been given. Further, through the courtesy of S. J. Crumbine, M.D., I have received the names of places in the United States that have been reported to him as having had milk-borne outbreaks of scarlet fever and diphtheria since 1923. By following these up I have been able, either through the state directors of communicable diseases or the local health officers, to obtain the age distribution in 11 outbreaks of scarlet fever and 2 of diphtheria.* Altogether a series of 21 outbreaks of scarlet fever comprising 1,362 cases, and 11 outbreaks of diphtheria comprising 709 cases have been collected. These outbreaks are listed in Tables II and III. No outbreak in which exposure was limited to a special age group has been included.

A higher incidence in children is generally accepted as a charac-

* In New York State 1917–1926

† New York State places of less than 200,000, 1915–1924, Vol. 1, *Annual Report* New York State Dept. of Health for 1925.

teristic of milk-borne typhoid fever outbreaks. In order to test the general truth of this observation and to ascertain its constancy, I have examined our New York data comprising 64 typhoid outbreaks, with 919 cases of known ages, attributed to milk-borne infection. These have been tabulated by age by individual outbreaks and then assembled for the entire series and the percentages by age periods calculated. The latter are presented in Table I, Column 1A. For comparison, the percentages by the same age groups for all typhoid cases in places of less than 200,000 in New York State are given in Column 1B. It is seen that 7.2 per cent of the milk-borne cases are under 5 years of age as compared with 4.5 per cent for all cases, an excess of 60 per cent. The excess is 27 per cent in the age group 0–10 years and 45 per cent at ages 60 years and over. Our figures therefore tend to confirm the observation that children are unusually liable to attack in milk-borne typhoid, but indicate that this liability is largely due to the excess at ages under 5. They further indicate that people over 60 years of age are relatively more subject to attack from milk-borne typhoid than younger people over 5 years of age.

Columns 2A and 2B show corresponding percentages for scarlet fever. Here we see that there is a slightly higher percentage of milk-borne cases at ages under 5 but markedly lower percentages at ages 5–9 and 10–14. The excess at age 0–4 is about 8 per cent, but the deficiency at 5–14 is 35 per cent. At all ages over 14 there is a consistently higher percentage of cases in milk-borne scarlet fever than in scarlet fever from all causes. It will be noted too that the relative excess grows greater with each succeeding decade as age increases.

Column 3 shows the corresponding percentages for diphtheria. We note that there is not an excess of milk-borne diphtheria at ages 0–4 but a deficiency of over 50 per cent. At ages 5–14 the deficiency is 25 per cent while in every age group above 14 there is an excess which increases relatively just as in scarlet fever.

Although, for reasons which will be explained later, the figures of certain outbreaks have not been used in calculating these percentages for scarlet fever and diphtheria, the omissions do not change the result much. It seems to be true then that a high age incidence is a general characteristic of milk-borne scarlet fever and diphtheria and not merely a peculiarity dependent primarily on an unusual age distribution in the consumers. Not only this, but it is much more marked than the incidence among children in milk-borne typhoid fever.

The next question is to determine how constantly this characteristic appears in individual outbreaks. Table II lists each of the outbreaks of scarlet fever for which satisfactory age data have been se-

cured. Three of these have not been used in calculating the percentages in Column 2A. The outbreak in Flint, Mich.,[20] was not used because the infection was transmitted through ice cream and therefore probably exposed a greater percentage of older people than milk ordinarily would. The Pittsfield, Mass., outbreak was excluded because there seemed to be a question as to the sufficiency of the evidence incriminating milk. While I do not pretend to have gone into the evidence in each of these out-of-state outbreaks, it has been fur-

nished and examined in several instances and in the others I have assumed that it was adequate because of the sources through which the age data came. The age distribution in this Pittsfield outbreak was so far out of line that it was queried and the response was not satisfactory. It was felt that in an outbreak of this size the exclusion of other possibilities should be made with considerable care before acceptance.

The only reason for excluding the Kalispell, Mont., outbreak was the grouping of all cases 30 years of age and over. The evidence was ample but the figures could not be used in calculating the percentages for the decades beyond 30, and their exclusion made very little difference in the percentages under 30.

Column 2 of Table II shows the ratio of the number of scarlet fever cases under 15 years of age to the number 15 years and over. For comparison, this ratio is given for all scarlet fever, regardless of mode of infection, as it occurred in places of less than 200,000 in New York State. Also, since the age incidence tends to rise as congestion decreases, this ratio is given for the unincorporated places only in New York State. Running down this column we find, aside from the Pittsfield outbreak, one (Buffalo) in which the ratio is less than that for all places less than 200,000. This ratio is probably a little higher than for the general run of cases in a city the size of Buffalo, but it certainly is not enough higher to be significant or to be useful as an indicator. In this outbreak the evidence incriminating the milk supply was quite conclusive. All of the cases were on one milk route; they occurred explosively; there was sufficient dispersion to make school or neighborhood contact improbable; and 6 unrecognized cases had existed for nearly two months on a dairy farm supplying milk to this dealer.

There are 5 other outbreaks in this list in which the ratio is less than twice that for rural New York. If we take this ratio as a criterion, this characteristic is present in significant proportions in 70 per cent of milk-borne outbreaks of scarlet fever. Applying this criterion to the 15 outbreaks of typhoid occurring in New York State since 1916, involving 19 cases or more each, there was a significant percentage of cases under 5 years of age in only 40 per cent of them. Under 10 years of age there were only 2 out of the 15 that had twice the percentage usually found in typhoid from whatever cause.

Table III is a table for diphtheria corresponding to Table II for scarlet fever. The figures of two outbreaks in this list were not used in calculating the percentages in Table I—the one in Rhode Island[11] because it was an ice cream outbreak and because the age distribution

beyond the 15th year was not given, and the Westchester County outbreak because it was transmitted by certified milk and hence largely limited to small children. The latter affords the *only* instance in which the ratio of cases over 15 was less than in the general run of cases either in New York State or in its rural districts only. The only other outbreak in which the ratio fell below twice that of rural New York occurred in Suffern, and here it will be noted that it approaches this criterion very closely.

It cannot be definitely determined whether a high ratio of adult cases of scarlet fever or diphtheria necessarily means milk-borne infection; probably it does not, even if outbreaks occurring among groups of adults in camps and institutions be excepted. A recent non-explosive outbreak of diphtheria in rural New York was confined almost exclusively to adults and was apparently spread by contact alone. Such an occurrence, however, would require somewhat exceptional conditions, and in this connection it should be remembered

15 and over	187	18	10	84	17	20

that a high percentage of young children is not an infallible indication of milk-borne typhoid. It is sometimes found in water-borne typhoid if the community has had either a high endemic rate or has been subject to outbreaks at short intervals. In an outbreak in Watervliet, N. Y., in 1917, out of 120 cases of known age, 28 per cent were in children under 10.

I have not attempted an explanation of the phenomenon, partly because of limited space, but principally because of the limited data on which to base or by which to test any theory that might be evolved. The most obvious theory, namely that the exposure of adults is increased *relatively* more than the exposure of children, does not seem to be borne out in the two small outbreaks (shown in Tables IV and V). These are the only outbreaks for which I could obtain a census by age of the dealer's customers.

TABLE V

DATA ON MEXICO, N. Y., OUTBREAK OF DIPHTHERIA

Ages Years	Total Persons on Route: Pop.	Not immunized	Attacked	Rate—non-immunized
Total	63 or 66	49 or 52	11	22 or 21
0–4	3 or 5	1 or 3	0	0
5–9	4	3	0	0
10–14	12	8	3	37.5
15–19	6	5	2	40
20 and over	38 or 39	32 or 33	6	19 or 18
0–15	19 or 21	12 or 14	3	25 or 21
15 and over	44 or 45	37 or 38	8	21

In the Deposit, N. Y., outbreak (Table IV), satisfactory data on the use of milk by each individual on the route were recorded.

It will be seen that the attack rate in adult milk drinkers is only about one-third less than in children. In the Mexico, N. Y., outbreak (Table V), the attack rate in adults is equal to or only slightly less than it is in children, making no allowance for the milk drinking habits at the different ages. These tables are submitted not because they prove or disprove anything, but merely to illustrate the kind of data we shall have to accumulate before the explanation can be reached.

In conclusion, I would say it will always pay to investigate the milk supply whenever an unusual *number* of adult cases of scarlet fever or diphtheria occur in a community. Suspicion should be excited by an unusual *number* of adult cases occurring within a limited period. Milk-borne outbreaks which are non-explosive do occur and a still greater number of them lack explosiveness in their beginnings. The practical application of this age characteristic therefore may lead, as it has in Edinburgh, to the early recognition of milk-borne scarlet fever and diphtheria and to correction of the cause.

The Tuberculous Worker and His Placement in Industry*

CHARLES W. BERGQUIST

President, Chicago Tuberculosis Institute; Superintendent Public Relations, Western Electric Company, Chicago, Ill.

IN considering the question of the tuberculous worker and his placement in industry, attention should naturally first be given to those points which would justify the consideration of this particular disease over other diseases.

During the past 25 years the mortality rate from tuberculosis has been reduced more than 50 per cent. Despite this continual and appreciable decline, tuberculosis is still the most destructive and fatal disease among wage earners throughout the United States. It is very prominent as a cause of death between the ages 15 and 44 years. About 1 death out of every 4 in this age group is due to tuberculosis.

Nearly two-thirds of all deaths from tuberculosis occur during that period of life when a person is of the greatest economic value to his family and yet is most insecure financially. Louis I. Dublin, Ph.D., in his recent book *Health and Wealth,* states that mortality rates for both sexes, although practically the same up to 10 years of age, are considerably higher for females than for males during the next 15-year period.

The white female rate is highest at about 26 years of age, when it is 138.3 per 100,000. The white male rate reaches its maximum at about 52 years of age, when it is 214.1 per 100,000.

Beyond the age 30 the rate for both sexes drops rapidly, and continues among white persons throughout the rest of life below that of males.

Although heart disease, pneumonia and cancer lead tuberculosis in causes of death among the people of the United States, tuberculosis really faces the competition of only heart disease. Both cancer and pneumonia are diseases which occur more frequently in an older age group, and they are different in cause and character. Four-fifths of all deaths from heart disease occur in the group over 40 years of age; in tuberculosis, death usually occurs at an earlier age.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 19, 1928.

The long period of illness resulting from tuberculosis makes it one of the most costly diseases both in the expense for proper care and treatment and in the money lost by the wage earner during his sickness. Moreover, the records of the Association for Improving the Condition of the Poor in New York City show that tuberculosis predominates as a cause of dependency.

Because of these facts, I believe it is entirely logical to give consideration to the detection of tuberculous employes, their proper placement and care, and a rehabilitation program for those who return which will make them eventually self-supporting and an asset to their families and to the community.

It has been estimated that a tuberculous patient is under care for an average of 2⅓ years. For an additional year at least he is probably unable to earn his normal wage. He is, therefore, during this entire period, a nonproductive workman, deprived of his income and faced with abnormal expenses for the treatment of himself and the maintenance of his family. It is quite necessary that during these years he be under close medical supervision which will help him to regain his place in industry. The rehabilitation program, therefore, has come to be recognized as the most important phase in the patient's after-sanatorium treatment.

Assuming at the outset that the patient will return to his former occupation if possible, the plans for his rehabilitation should go forward while he is in residence at the sanatorium—and if possible should be considered a part of his treatment.

INDIVIDUAL RESPONSIBILITY

Generally speaking, tuberculosis is most prevalent among families with small incomes whose home conditions and environment are not conducive to the building up and maintaining of body resistance.

Unsatisfactory working conditions may tend to stimulate a tubercular lesion already present, but the position and habits of life of the patient outside his working environment doubtless play a more important rôle in his disability. The 8 hours now generally accepted as the working day are not as responsible for tuberculosis as are the 16 remaining hours in which the individual follows his own inclinations. In commenting on this phase of the subject, the editor of *Nation's Health* made the following editorial comment about a year ago:

> Tuberculosis among industrial workers has always been an interesting health problem and often a controversial one from the standpoint of social and economic responsibility. It is an accepted fact that tuberculosis does not arise from industrial processes any more than do measles, scarlet fever, or other communicable diseases.

The workman's environment in early life has a profound influence on his later years as far as this disease is concerned, for we know that in many cases the infection has taken place in childhood.

Such studies as have been made in individual factories, presenting no special hazards, have shown a tuberculosis rate comparable to the general community, or about 2 per cent.

Because of the comparative ease with which industry can provide facilities for diagnosing tuberculosis and other disabilities, it has a certain responsibility in the matter. But until the personal responsibility and social environment of the patient have been properly evaluated, industry should not be charged with both social and economic consequences of this disease.

SANATORIUM TREATMENT MOST EFFECTIVE

There are three essential facts to be considered in connection with a study of tuberculosis. Tuberculosis is communicable; tuberculosis is preventable; tuberculosis is curable. The earlier the diagnosis, and the sooner the treatment is started, the better is the chance for recovery.

Without proper treatment the progress of the disease cannot be combated successfully, and authorities agree that there is no place where a patient with tuberculosis can be treated so well and learn so much about taking care of himself as in a good sanatorium.

If adequate facilities for the treatment of a case can be found in a nearby sanatorium, the patient will gain several advantages: Transportation expenses will be reduced; visits from members of the family can be more frequent, thus helping to develop a good mental attitude on the part of the patient; the physician representing the industry in which the patient worked can follow the progress of the case much more effectively; and in many instances there will be less opposition from the patient himself if he knows that the sanatorium to which he is going is not located at any great distance from his home.

Dr. Allen K. Krause, Editor of the *American Review of Tuberculosis,* and on the staff of the Johns Hopkins Hospital, is authority for the following statement:

> The day when tuberculosis sufferers went to other climatic regions for treatment is passing and the trend of treatment of tuberculosis during the last generation may be summed up in one word—" sanatoria."
>
> For a long time the trend has been away from climatic treatment. It has been established that the tuberculosis patient in all stages of the disease can regain health or be greatly and permanently improved by the proper treatment near home in practically every section of the country. Nevertheless, for those who can afford it, the right climate to be selected for the individual case has certain advantages.
>
> The best of climates is not to be recommended for any patient who might suffer any undue strain in mind, body or purse to obtain it. For practically every patient, the proper treatment means sanatorium treatment at some time during the

course of the disease, this preferred at the beginning in nearly every case. To delay or temporize is to court disaster and eventual failure.

The leading medical authorities agree that hospitalization of the tuberculous has played an important part in the decline of this disease. It has been stated that the death rate from tuberculosis is lower in communities showing the highest average hospital days per tuberculous patient. It is quite important, therefore, to impress upon the tuberculous patient the advantages of sanatorium treatment versus treatment at home. The added expense of sanatorium treatment would be justified in the earlier return to work and financial independence of those afflicted with the disease.

Close observation must be maintained not only up to the time when the patient may be discharged from a sanatorium but during the subsequent periods when, under the supervision of a physician or skilled social worker, he is being trained gradually to return to his former occupation. The usual penalty for the lack of such supervision is a probable recurrence of the trouble with less probability of recovery.

PHYSICAL EXAMINATIONS

In the industry with which I am associated there was an apparent increase in 1927 in the number of incipient tuberculosis cases among the 25,000 employes, one-third of whom are women. However, a detailed study and analysis of all cases proved that this increase in the number of cases reported was due not to unfavorable working conditions but to a policy of the medical department to examine thoroughly for potential tuberculosis every employe who reports to the hospital because of illness, especially of the respiratory type.

In the physical examination of new employes special attention is given to the lungs and respiratory tract in order to detect any possible tendency toward tuberculosis.

In any industry, occasionally cases of tuberculosis will develop despite precautions. When such a case occurs, every effort should be made by the employer to assist the employe in his fight for health.

Many of the larger cities maintain and operate tuberculosis sanatoriums. The Municipal Tuberculosis Sanitarium of Chicago is such an institution. It is operated under the direction of a board of trustees of which the health commissioner is a member. This sanatorium enjoys a reputation for efficiency and high professional standards.

However, it usually is not possible for any municipality alone to provide adequate facilities for all the tuberculosis cases in the community. Industry, therefore, should establish a close contact with some recognized private or semi-public sanatoriums where industrial cases may receive proper treatment.

If we are to make further progress in the fight against tuberculosis in industry, industry itself must stand ready to support these institutions and their local tuberculosis associations.

Whole-hearted participation in such activities will bring dividends in community good will, lower manufacturing costs for the industry and better employe relations.

Naturally, in deciding upon the amount of financial assistance that the employe needs to secure adequate treatment, the employer must consider the patient's obligations to his family as well as his ability to finance himself during an illness which will last at least 6 months and may extend over a period of 1 or 2 years.

If an employe is eligible through membership in a company plan mutual benefit association, or disability insurance, to receive sickness benefits, any further help from the employer should be determined largely by the employe's family obligations and his available financial resources. In any event he must not be denied prompt and proper treatment for the disease.

Experience has taught us that it is advisable to discharge a patient from a sanatorium as soon as the case has been arrested. This practice is very effective in helping to maintain a good mental attitude. At the same time, the average patient at this stage has not usually recovered his health to the extent of returning to his former occupation on a full-time basis.

The real value to the man, in so far as his mental attitude is concerned, comes from the fact that in leaving the sanatorium he is returning to his former environment. This is effective in assuring him of the employer's desire to place him again at his former work as soon as he is physically able to perform it.

An employe with an arrested case of tuberculosis should not believe he must be treated differently from other people. He is not a menace to his associates even though occasionally there exists an impression that he is.

Drs. Vogeler and Lyman and many others have for years recommended that, wherever possible, the employe should endeavor to readjust himself to his old occupation.

In the book, *Advising the Tuberculous about Employment,* by Hamilton and Kidner, the following paragraph appears at the beginning of the chapter, "Selecting an Occupation":

> Generally speaking the tuberculous adult should be advised to seek employment in which he can capitalize the knowledge and skill gained through his previous life and employment experience. . . . A complete change of occupation is advisable only when there exists in the former occupation hazards known to be dangerous for the tuberculous.

In leaving a sanatorium, an employe is confronted with the problem of his medical supervision during the period of his readjustment in industry. This should rest with a representative of the medical department where such service is maintained by the industry, or with a physician who may be delegated for this specific work. During the time the employe is in the sanatorium, this representative should follow the case so that upon his release a rehabilitation program may be inaugurated with which the employe is in full accord. Throughout this training program, the length of which will vary with the physical condition of each employe, the medical department should give the employe frequent physical examinations and at least once a year a complete examination by a tuberculosis specialist.

If this supervised program is to be successful, it must include three aids to complete physical and vocational rehabilitation:

1. A hardening-up process of a somewhat more continued and scientifically constructed character than can be carried on at a sanatorium
2. A vocational training adapted to the patient's needs and temperament
3. Placement in work best suited to the patient's own physical condition and training

To insure the best results from such a rehabilitation program will necessitate an expenditure of money sufficient to meet the difference between a normal wage and the amount the employe may receive during the time he is being readjusted to industrial life. This expense is justified on the ground that such a program will shorten the period of absence after discharge from a sanatorium.

CONCLUSION

In conclusion let me briefly summarize the various points which I have attempted to emphasize throughout the presentation of this paper:

1. Tuberculosis is still the most destructive and fatal disease among wage earners.
2. Tuberculosis is communicable, preventable, and curable.
3. After an early diagnosis of tuberculosis is confirmed, it is necessary that the patient receive prompt treatment.
4. Successful treatment requires supervised care, preferably in a sanatorium.
5. The death rate from tuberculosis is lowest in communities showing the highest average hospital days per tuberculosis patient.
6. Lack of accommodations in free tuberculosis institutions makes it necessary for industry to support and coöperate with private sanatoriums.
7. It is not only safe but advisable for an employe with a controlled, arrested case to return to his old occupation.
8. During a training period when the employe is being readjusted to his former work, a rehabilitation program should be carried on under the supervision of a carefully selected and trained personnel.

So much has been accomplished by the medical profession, municipal health authorities and such organizations as the National Tuberculosis Association and its affiliated bodies in the prevention of tuberculosis through education and clinics, that industry must now take its part in caring for employes who become afflicted.

The far sighted industrial leader will incorporate in his program of curative measures a very definite plan for the rehabilitation of arrested cases. This will be done not only for economic reasons but for humanitarian reasons.

Just as industry has reduced accidents and has found that it pays, so will those same industrial leaders learn that a reduction in time losses through sickness will likewise pay real dividends.

DISCUSSION *

C. W. Bergquist, Chicago, Ill.—I am not a physician but I am connected with a large Chicago plant which employs 25,000 to 35,000 workers, one-third of whom are women, and which has had an extensive medical and nursing department for twenty years. We find that preliminary medical examinations, which have been made for years, are very helpful to our employes as well as to the plant, and many persons predisposed to tuberculosis have been kept from working in situations which might have been hazardous to them. I take a decided issue with those who think industry should take no part in health education in a broad way.

Emery R. Hayhurst, M.D., Ohio State University, Columbus, O.—The survey by Mr. Coleman has shown that the industrial side of the problem of tuberculosis is realized in many parts of the country. Since the tuberculosis program is " sold " to the public it is decidedly advantageous to make use of it for advances against the 2 per cent or more tuberculous found in industry. The tuberculosis dispensary may well refer the cases found to the industrial medical service of the plants so equipped, which services ought to check up health hazards, particularly in regard to ordinary ventilation, overheating and stagnation in work places. But the dispensary should refer the case which comes from a small plant directly to the local health authorities, who should investigate the work place. I would not imply that the work place is the sole cause of the promotion of tuberculosis, but the 8 to 10 hours a day spent at work usually have a direct influence in the downhill course of the case.

I think the Philadelphia plan is to be commended to other cities. It has been pointed out that the rise and fall of tuberculosis mortality in England for the past 75 years is an economic problem—hard times, and even political measures, which depress industry, invariably resulting in higher rates.

While at the Dublin Congress at the Royal Institute of Public Health this summer, I heard a very interesting paper by Dr. P. C. Varrier-Jones, Director of the Papworth Village Settlement for Tuberculosis, the paper being accompanied by two films of the colony and its factories. There are some 2,000 tuberculous indi-

* Discussion here presented covered, not only Mr. Bergquist's paper but also Extension of Industrial Hygiene by Tuberculosis Associations in the United States, by Bernard S. Coleman, in the February issue, page 157.

viduals now employed in this colony, where the families also live, and all are under constant medical supervision. Such a colony demonstrates that a tuberculous person can work at various factory processes and improve in condition at the same time. Economic, social and psychic factors are all satisfied. Of course, the object of this colony is the cure of tuberculosis first, and manufacturing production second, although it is practically paying expenses.

The post-war industrial depression in Great Britain has appeared to result in lessened morbidity and mortality, probably because workers are out of the factories and in the open air, and the "dole" system is undoubtedly benefiting many of them. However, it is necessary to wait to see the effects on the tuberculous. I think we should regard tuberculosis as universal in the human race, much the same as weeds in the garden, and that it is only by constant supervision and "cultivation" that we can keep the disease down.

Many positive results have already been obtained through industrial efforts such as those pertaining to the printing and publishing industry. I am not convinced that the work place is the only place to search for tuberculous persons associated with a given plant, because only those who are at work at the time or period are examined, while past workers and occasionally those absent are overlooked. We would not think of gauging the status of measles in a community by the number of cases found in the school house at a given time, but we would search the neighborhood and look for past cases, and I think such should be done in searching out the industrial relations of tuberculosis.

Eugene L. Fisk, M.D., Life Extension Institute, New York, N. Y.—I have an idea that the peak rate of tuberculosis among young women appears unduly prominent because any publicity concerning women is easy to get. The real question is whether the tuberculosis rate for young women is decreasing more slowly than for young men.

J. A. Goldberg, Ph.D., New York Tuberculosis and Health Association, Inc., New York, N. Y.—We have been making a study of tuberculosis in the rock drillers of New York City, those in connection with foundation construction work, subways, etc., and we find that they suffer from silicosis and from tuberculosis. The medical side of the investigation has been conducted by Dr. Haven Emerson's Department in Columbia University. The report is shortly to be published in the *Journal of Industrial Hygiene,* but at this time I am able to state that the reported 2 per cent found in industry is far too low for those on this job; also, we could not get at many who were away from the job, sick at home, etc.

Daniel J. Kindel, M.D., Consolidated Coal Company, Inc., Fairmont, W. Va.—Dr. Wright has thrown a bomb shell by estimating industrial tuberculosis at 5 to 10 per cent instead of 2 per cent or lower. My company, which employs about 10,000 workers, would, therefore, have possibly 500 employes with active tuberculosis. It is a huge problem at any percentage, but we want a very careful study before we accept these figures. While our preventive medical service is still young, we have so far found nothing like this rate.

Eugene L. Fisk, M.D.—I know of an instance where a plant employs 10,000 workers with "no tuberculosis," according to the plant physician. Hence, why worry!—There is a lot to do here and we cannot feel overly proud of the country's record thus far. The "periodical health examination is a murderer," some say, but is this an emotional disturbance or a fact?

Wade Wright, M.D.—I am not a pessimist in any sense of the word. However, Dr. Kindel selects workers for coal mining, and the coal fields have always been known to have a low tuberculosis rate. I insist that the 2 per cent usually found does not show the true situation. It is probably nearer 5 per cent. The Metropolitan Life Insurance Company, after pre-employment examinations, sends about 200 persons a year to its sanatorium. Do not be deceived regarding the greatly decreasing prevalence of tuberculosis despite a declining mortality.

Volney S. Cheney, M.D., Medical Director, Armour & Company, Chicago, Ill.—The industry has a part to perform in taking care of tuberculous employes, but only a small part—healthful working conditions. Leave the home relations and social aspects to outside agencies organized for that purpose. Such is not a part of industry's job, although industrial managers from a humanitarian standpoint often do this. By many the individual is considered a part of the industry, but I say he is only a temporary part; this is, while he remains there. Hence, why take complete care of him? The insurance company is more concerned than industry in this. At present we have a difficult time in advancing the industrial medical department because it cannot show definitely where it pays, as in the case of other departments in the plant. We receive tuberculous cases from the Chicago Tuberculosis Institute and its dispensaries and coöperate by placing them in the most favorable locations in our plant. We ought to examine our employes more often, at least twice a year, but with 12,000 employes and a labor turnover of 150 a day, because our employes are proverbial floaters, we cannot afford to do it. Many of our workers are reëxamined several times a year as it is, since they go from one plant to another. Let the laborer share part of this burden and the industry will do its part.

A. J. Lanza, M.D., Metropolitan Life Insurance Company, New York, N. Y.—The points of view here presented are not so far apart as might be thought. Each speaker gives only his own experience and viewpoint and these tend to distort the whole picture. The intelligent employer (and the big employer is usually an intelligent employer) is more and more recognizing that the employe's health and welfare is an industrial responsibility. It is there whether he likes it or not. The employer is forced to recognize it because of economic pressure. In Chicago I saw a plant employing 800 high-class machine tool workers where, to maintain their production, the management gives attention to many things, such as the food eaten by the employes, illumination, ventilation, even the use of the newer type of window glass admitting ultra-violet rays, annual examinations of the eyes, etc., etc. All this is done because they feel it helps them to meet competition and to maintain their reputation for reliable goods.

Eugene L. Fisk, M.D.—The touchstone is evidently coöperation, not paternalism. The employe is a copartner and, if treated so, he will stay on the job; therefore his health interest, from all points of view, is a part of the necessary organization.

Tuberculosis in Racial Types with Special Reference to Mexicans*

BENJAMIN GOLDBERG, M. D.

Municipal Tuberculosis Sanitarium of Chicago, and the Department of Pathology and Bacteriology, University of Illinois College of Medicine, Chicago, Ill.

THE health of the people is the supreme law." The physical and mental stamina of the individual determines the physical and mental stamina of the race. One would suppose that legislators and lawmakers, both state and national, who are responsible for the peace, happiness and prosperity of the state and nation, should also be responsible, in the larger sense, for national public health, without which there can be neither peace, happiness, nor prosperity. Comparatively few physicians seriously enter the field of politics and comparatively little attempt is made by the medical profession to influence legislation in the matter of big race health policies.

If it is a question of importing livestock from abroad, special consideration is given to the quality of the stock, the breed, the ancestry, prevalence or absence of disease or epidemics, and the susceptibility of the given breed to epidemics or disease in their new environment. Even in the matter of livestock shipments between the states, certain laws and regulations are enforced for the purpose of protecting the animals which will be exposed to the new arrivals.

Let us now consider human immigration. To the eye of the public health man the barriers and weirs erected in the stream of human immigration are inadequate and too few. The stream is not analyzed for its health inheritance, for its resistance to disease, for its health reaction to its new environment.

Fortunately, the health inheritance of our immigrants, for the most part, is the health inheritance of the older, civilized races. Most of the races admitted have run the gamut of disease, have had bitter experience with tuberculosis, syphilis, acute contagious diseases, have, perhaps, as far as the individual disease is concerned, gone through the ordeal of the "survival of the fittest," have lost uncounted numbers of susceptibles and finally, at the end of a trail beset with suffer-

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

ing and disease, have reached the haven of comparative racial immunity. Some of the European peoples coming to our shores, for instance the Swedish and Irish, have not, perhaps, passed all the way along the trail.

There are, however, other races not of the old European stock, who seek admission to the United States, whose entrance in considerable numbers must under present circumstances be considered as a public health menace. The public health man is not inclined to accept the famous saying of Thomas Jefferson at its face value. If Jefferson had been conversant with present-day problems in public health, he would have had to modify his statement that "all men are created equal."

The official interested in public health must realize, as a first principle, that all men are not created equal; that there is no equality between either the health of individuals or the health of races; that there is a health heredity as part of the biologic heredity; and that health heredity is vitally different in different races. Even the health heredity of the various population units in the United States—the difference in racial susceptibility to disease—has always been with us a burning public health problem.

The Indian, within the confines of the United States, met civilization and was overwhelmed by the diseases of the white man. He was unsuited in every way for urban life. He alone was the loser; his race died out without serious repercussion on the health of the white man.

The negro offers a public health problem of a different nature. Prior to his contact with white civilization, and immediately after his entrance into this country on the plantations of the South, he was practically free from tuberculosis. Today the negro is tending more and more toward urban life, and coming in greater and greater numbers to highly tuberculized communities. Frequently he is infected with tuberculosis in the urban centers and spreads infection both among his own race and among the whites.

In Chicago, in 1927, the negro mortality was 401.8 per 100,000, over 6 times the mortality of the white race. Nevertheless, he is adaptable and in time will, without question, develop sufficient relative immunity to enable him to cope successfully with city life. Meanwhile, the process of immunization is costly. The care and supervision of the negro in the matter of tuberculosis alone over the time during which he is increasing his resistance to civilization diseases necessitates the expenditure of huge sums of money.

At the present time in Chicago we have 8 tuberculosis dispensaries for the entire population, and of these, 3 are devoted almost entirely to the service of the negro. This means that while the negro consti-

tutes only 5 per cent of our population, he is receiving 37 per cent of our tuberculosis service. Last year $836,021.30 was expended by the Municipal Tuberculosis Sanitarium for field work in Chicago. On the basis already stated, $309,327.86 was expended on the negro receiving the services of these 3 dispensaries.

The negro, as an essential element in our American population, is entitled to this greater consideration, and this increased expenditure. He is an American citizen, entitled to all the prerogatives and rights of such citizenry. Both for his own sake and for the sake of the white race his problem must be met as effectively as possible; he must be given, during his probationary period in urban life, all the safeguards that science can command.

There is, however, another race which has no demand on us and which is rapidly introducing among us a health problem as serious as or even more serious than the health problem of the negro. I refer to the Mexican. We seem, throughout the United States, to be asleep to the menace of the immigrant Mexican. Confronted with the problem in Chicago, I took occasion to investigate the literature and was amazed to find that practically no consideration has been given to this problem in this country. In view of this, I took occasion to write to the health officials in states and communities which have a large Mexican population and was surprised to learn that even in those communities in which the Mexican was admittedly a most serious health problem, no thorough data had been compiled and no effective remedial measures even suggested. The Mexican is coming in thousands, bringing with him his health standards, his susceptibilities, bringing potentialities for deterioration in national health which few of us even begin to realize.

TUBERCULOSIS IN THE PRIMITIVE RACES

Before going further with the subject of the Mexican as a health menace, it may perhaps be advisable to roll back a few pages of history and study the reaction of the so-called primitive races to civilization and to its diseases, particularly tuberculosis.

The American Indian—We see very little in recent literature concerning tuberculosis and the American Indian. The Indian has, unfortunately, solved his own problem—he is dying out. However, in the literature of a couple of decades ago, many terrible descriptions are available concerning the inroads of tuberculosis among the American Indians.

Coming down to recent times, we find that in the mortality tables covering the U. S. Registration Area for the year 1924, the total mor-

tality from tuberculosis in Indians was 680.3 per 100,000. The estimated total population of the Indian in the same area in 1924 was only 98,920, and of this number 673 died of tuberculosis in one year.

Further examples, considering tribe after tribe, might be furnished to demonstrate the devastation wrought by tuberculosis among American Indians. The Indian, as explained, was the only one to suffer. Fortunately for the white man, the Indian was inadaptable to city life; he did not migrate to the city, and did not, in consequence, broadcast tuberculous infection among the whites. If he had developed the qualifications of a city dweller, the Indian would have constituted a serious public health problem; he would have added fuel to the flames, thrown oil on the smoldering embers and, undoubtedly, many of his white brothers would have been consumed with the Indian in the conflagration.

This is a point not sufficiently realized. It may be thought because the Indian, ravaged with tuberculosis, has had little influence on general health in the United States, the same proposition will hold concerning the negro and the Mexican. It must be emphasized, however, that the negro and the Mexican do not live apart in reservations; they live in densely populated urban centers in contact usually with the lower grades of the white race. These classes of whites, owing to economic conditions—food, housing, etc.—are the members of the white race most prone to tuberculosis. It must be quite obvious then that the increased tuberculosis morbidity in the negro and the Mexican will have its repercussion on that portion of the white race which comes into close personal contact with these susceptibles.

The Filipino, the South American Indian, and the native African all have had cause to regret the white man's civilization. The ravages of tuberculosis in these and other primitive races have been in direct proportion to the degree of intimacy and contact with the coughing white man.

The Negro in This Country—As already intimated, the negro in the United States constitutes a tuberculosis problem entirely distinct from that of the Indian. The negro is rapidly being urbanized, and this undoubtedly increases the tuberculosis mortality and morbidity in the negro race.

A review of the situation must make it clear that this urbanization of the negro cannot take place without having a deleterious influence on public health in general. The negro from the South is being swept in ever increasing numbers into highly tuberculized communities. He there meets infection and is infected; he there also helps to spread infection. He has many points of contact outside of his own race, and

acts as a medium for further dissemination of tuberculous infection in the community. The negro tuberculosis mortality in Chicago is double or treble what it is in the cities of the South. For instance, in 1926, in Mississippi, it was 161 per 100,000 as against a negro mortality in Chicago of 389 per 100,000 in the same year.

Notwithstanding an intensive campaign, and despite all measures at our command, the tuberculosis death rate in Chicago has, during the past few years, shown a slight increase. The lowest tuberculosis death rate recorded for the City of Chicago was in 1922 when the rate was 78.3 per 100,000. This rate has gradually risen until in 1927 it reached 82.7 per 100,000. Statistics indicate that this rise is due to the greatly increased number of susceptibles in our population.

The outstanding fact revealed by these figures is that among the white elements in our population, the mortality rates have definitely improved. The improvement, however, is not reflected in the general mortality rate because it is more than offset by the increased tuberculosis mortality in the negro.

Mexicans—In 1927, 68 Mexicans died of tuberculosis in Chicago. These Mexicans were classed as white on the death certificates; therefore, in estimating our white mortality we must deduct these 68 Mexican deaths.

In discussing the magnitude and complexities of the negro health problem we have but one object in view. Public health men throughout the country understand and evaluate this problem with sufficient precision. It is used merely as a yard stick for the measurement of another tuberculosis problem which menaces us, and which, if steps are not soon taken, will prove even more serious than that of the negro. The Mexican of tomorrow will bring to our towns and cities dangers which will strain the resources of the local and national public health agencies to the utmost. We have discussed the subject of tuberculosis in primitive races merely to bring out the ravages among the Mexicans as they go through the process of urbanization. We have tried to indicate that in this process the Mexican will not be like the Indian, for he will not suffer alone; he will be infected and in turn will broadcast tuberculosis in the community. Like the negro he has and will have many points of contact with our native American population. As Mexican immigration increases he will have still more points of contact. It is a question that we must face now or submit to serious consequences later.

Shall we allow the Mexican, who has no claim on us, to develop in our midst the same serious problem that the negro, who has a claim on us, has developed? Shall we allow the unrestricted immigration

of susceptible aliens? Shall we allow them to go through the process of urbanization in our communities, and to undergo the complex, little understood and tedious process of resistance development? Are we logical if we protect with one hand and destroy with the other? Are we logical if we try to use all scientific means to protect our native American population from tuberculosis, and at the same time allow an unrestricted stream of susceptibles to enter our communities to become exposed and to kindle the fires as fast as we extinguish them?

PRESENT STATUS OF IMMIGRATION LAWS

Until 1924, Mexicans were permitted free entry to the United States. Starting in 1924, the Mexican immigrant was required to pay an $8.00 head tax and a $10.00 visé fee. He was also supposedly obliged to pass a medical examination and literacy test, but this has not been enforced. He was, strange as it may seem, not on a quota as are the European nations.

Statistics quoted by Kenneth L. Roberts in articles appearing in the *Saturday Evening Post* show definitely a marked increase in Mexican immigration. In 1907 only 91 Mexicans entered the United States through the portals of legal entry. In 1926, 66,000 Mexicans immigrated to this country. In addition, all authorities concede that at least as many Mexicans enter the United States illegally as enter legally each year.

MEXICAN POPULATION IN THE UNITED STATES

In the opinion of Mr. Roberts, there are at present in the United States 3,000,000 Mexicans, that is, individuals either born in Mexico or with one or both parents born in Mexico. This estimate does not, of course, take into consideration the great population of the Southwest, which is of Mexican descent.

Since 1920 the stream of Mexican immigration has steadily increased. The immigrants, pouring first into the Southwest, California, the orange groves, the industries and mines, later, in ever widening circles come to the beet fields and orchards of Michigan, and to the factories and mills of Detroit, St. Louis, Chicago. The fruit and vegetable growers of the Imperial Valley of California, the industrialists and mining magnates of the Southwest, the railroad magnates, the factory owners, the industrialists of the West and Middle West, must have their Mexicans. The good news travels. The Mexicans in their native country hear of riches, opportunity, good food, free hospitals, and free medical care in the United States. They hear that they can earn in a day what they cannot earn in a week in Mexico.

They are not bothered by the head tax or the visé. The Rio Grande is long, their hopes are high, and they come to the Eldorado.

Good health and proper living standards are related. What are the Mexican's standards of living? In Chicago he lives either in the box-car or in the colony.

If he makes his home in the box-car he lives where his job is. Half a dozen or more obsolete box-cars are drawn up on an unused railroad siding; they have been slightly altered and furnished in primitive fashion for habitation purposes. There is usually no provision for light or ventilation except by means of the door. As space is a consideration, as many Mexicans as possible are crowded into a restricted space. There is, of course, no running water, in fact, very little of any kind of water, and there are no toilet facilities. The Mexicans in these box-cars are in the position of Trudeau's rabbits in the cellar. Susceptible as they are, it is difficult for them, under such circumstances, to escape infection if one of their number is tuberculous.

The Mexican colony is a crowded, unhygienic home, where there are congestion, open tuberculosis and exposure.

THE TUBERCULOUS MEXICAN IN CHICAGO

Though there are many other health problems which the Mexican brings with him, this paper is confined to the problem of tuberculosis. In 1927, 387 Mexicans were admitted to the general wards of the Cook County Hospital. The situation became acute and it was borne in on us that energetic measures were necessary. A survey was consequently planned and carried out along the following lines.

The nurses were first sent out into the districts and instructed to locate, as far as possible, the Mexican families. Five nurses and five physicians were assigned to the work. The nurse first called on the families and made appointments for examinations. The physicians who did the examining called, for this purpose, either in the evening, on Saturday afternoon or Sunday morning. It was realized that home calls made by the physician during regular working hours would be ineffective; the wage earner, who was often the affected one, was at his work in the railroad yards or the stock yards and could not, of course, be examined.

In this survey, out of a total of 1,197 Mexicans examined, 24 were diagnosed as tuberculous, and 254 were placed under observation as suspects. In other words, 2 out of every 100 Mexicans examined were affected with tuberculosis, either pulmonary, bone or gland. According to these figures the morbidity in Mexicans is 10 times greater than that in the general population.

In 1928, there were 534 Mexicans under the supervision of the Municipal Tuberculosis Sanitarium. Of these, 380 were classified as observation cases or suspects; 154 were definitely diagnosed as tuberculous, of whom 83 were cases of pulmonary tuberculosis. Accepting the Consul's estimate of 7,000 Mexicans in Chicago, we have, therefore, a ratio of 12 pulmonary cases for every 1,000 population. This figure is to be compared with the ratio of 3 pulmonary cases per 1,000 population, considering all nationalities.

The mortality rate indicates a truer picture. In 1927, 68 Mexicans died of tuberculosis in Chicago. From these figures we are amazed to note that 12 Mexicans died of tuberculosis in Chicago for every 1 Chicagoan of the general population who succumbed to the disease.

A detailed study of 230 charts of the pulmonary cases showed that 93 per cent of the patients in question were in Chicago for a period of 5 years or less; 86 per cent were in Chicago 4 years or less; 24 per cent, or one-fourth of the patients, had been in the community less than 1 year. It must be unequivocally evident, then, that the Mexican in Chicago, as elsewhere, is a serious social liability.

As a further check-up a survey of the Mexican patients treated in the tuberculosis ward of the Cook County Hospital was undertaken by one of our dispensary physicians, Dr. J. J. Mendelsohn. It was found that Mexican admissions for tuberculosis amounted to 15.2 per cent of the total Mexican admissions to the hospital.

With regard to the occupation of these 63 patients treated at the Cook County Hospital, the tabulation brought out the fact that practically all the Mexicans were unskilled laborers. The Mexican is below medium stature, of inferior muscular development and under excessive labor demands will rapidly break.

It was found that 85 per cent of the patients were in the later stages of the disease when admitted to the hospital. It is evident, therefore, that the Mexican is difficult to reach with public health measures. He shuns doctors and clinics and spreads infection freely in the community until forced, by absolute physical disability, to seek help.

It was found that 19 per cent of the Mexicans in the tuberculosis ward of the Cook County Hospital had been in Cook County less than 1 year. Thirty-seven, or 64 per cent, had resided in Cook County for a period less than 3 years. The mere statement of these facts should be sufficient to emphasize the urgency of our Mexican tuberculosis problem. At the present time we have a population of only about 7,000 Mexicans. This population, however, is rapidly increasing, re-

cruited from the west by primitive Mexican stock coming to Chicago as transient labor.

In 1927, 50 Mexican-born patients died of tuberculosis in Chicago. Of these 50 patients 32, or 64 per cent, died as charity patients in the Cook County Hospital. While statistics on the point are not available at the moment, it is safe to say that practically all of the remaining 18 patients were subjects for charitable care and assistance.

It was found that 47 per cent of the patients died within 1 month after admission. The summary of Mexican deaths from tuberculosis brings out two facts: First, it emphasizes the observation already noted that the great majority of patients come to Cook County Hospital in the advanced stage of the disease; and second, that the Mexican, like other primitive races, is subject to acute and subacute types of tuberculosis.

Our tables also indicate a progressive increase of Mexican deaths in our charity institutions. In 1922, with an estimated Mexican population of 2,500 we had 12 Mexican deaths from tuberculosis at the Cook County Hospital, while in 1927 from a Mexican population of 7,000 we had 32 tuberculosis deaths in Cook County Hospital. In each instance, therefore, 5 Mexican patients died in the Cook County Hospital for every 1,000 of Mexican population. We see, consequently, that the problem multiplies as the Mexican population multiplies and in exact, direct ratio.

SUMMARY

Our political and social leaders are not sufficiently interested in the race problem as it affects health. The industrialist and agriculturist in the West and the Southwest, in importing Mexican laborers, are also importing a race "sizzling with susceptibilities." In view of this fact a thorough physical examination of every Mexican immigrant is a public health essential.

The public health official is "tilting at windmills" in his attempt to reduce tuberculosis mortality if tuberculous susceptibles are allowed to flock into his community in droves. The Mexican will not, like the Indian, suffer or die alone, but will increase dissemination of infection in the community in which he was infected.

The immigration laws which restrict the quota of some of the older European peoples, comparatively immune to tuberculosis, are not effective in restricting the immigration of Mexicans, a race highly susceptible to tuberculosis. The gain to the industrialist in cheap wages is more than counterbalanced by the loss to the taxpayer in increased charity expenditure.

The 7,000 Mexicans already in Chicago constitute a problem. Who will solve the problem when the Mexican population amounts to 200,000 or 300,000? With an estimated negro population of 170,000 it has been found necessary to devote 3 of our 8 dispensaries, or 37 per cent of our entire tuberculosis facilities, to the care of the tuberculous negro. The Mexican in urban life, according to figures available, is even more susceptible than the negro. An increase in Mexican population to 150,000 or 200,000 would practically monopolize the remaining 5 dispensaries. As dispensary operation costs on an average $104,502.66 per year for each dispensary it will be readily understood that the increased expenditure will be an enormous drain on the taxpayers.

REMEDIAL MEASURES, IF ANY

We have considered the problem from its various angles. Is there any remedy? The pessimist will say that the problem is out of the hands of the public health officials, that immigration officials and political leaders are not sufficiently impressed with the seriousness of the question to propose or enforce sufficiently energetic measures.

We believe that at least some of this laxity on the part of our lay officials can be laid at the door of public health and professional men. We do not make sufficient effort to educate the members of our state and national legislative bodies concerning the important health questions of this kind. We have made no effort, as far as I am aware, to reach the industrialist and agriculturist who are prime factors in the importation of Mexican labor. They can, however, be convinced that their success and prosperity are bound up irrevocably with the health and prosperity of the community and that part of the taxes for increased charitable expenses will have to come out of their pockets.

Health agencies, municipal leaders and the officials of social agencies should make greater effort to gather dependable statistics relative to Mexican immigration. They should present these statistics through the proper channels at Washington and allow the figures to speak for themselves. This should result in placing on the statute books an immigration law which would cope not only with this situation but with any subsequent public health problem of a similar type that may arise, and would in some measure offer a health protection to the American citizen.

All peoples of all races seeking admission to the United States should be subjected to thorough physical examinations, and in those races that are susceptible to special diseases, as is the Mexican to tuberculosis, special attention should be given to that particular disease.

Almost every large city in this country has, in its sanitary code, housing laws which should protect the individuals adequately against the danger of a contagious or infectious disease through congestion or overcrowding. Laxity of enforcement of such regulations should, in the presence of a menacing condition, be laid at the door of the health officer responsible for such enforcement. The box-car on the railroad siding should come under this category and be controlled from this standpoint. In the event that interstate travel is an evading issue for this type of movable home, the U. S. Public Health Service would, we feel certain, control such a situation.

If adequate housing facilities were provided by the industries utilizing this type of labor, and individual segregation in the home were possible, a lessening of congestion would result in a lessening in the spread of disease.

The industrialist, educated to the danger which occurs in the employment of basic, primitive races, should be educated further to provide an adequate medical inspection and examination service in order to detect the disease in its early stage, and weed out the physically unfit, thereby also preventing the spread of the disease.

Our federal statutes allow the deportation of any individual who enters this country, resides here for a period of less than 5 years, and becomes a public charge by virtue of physical disability or other cause. This deportation legislation, unfortunately, is not utilized to the extent that it should be in the various communities throughout this country, and consequently the financial burden in such communities, from the public health standpoint, becomes very large.

CONCLUSION

We in Chicago, as in other cities throughout the United States, are face to face with a special menace, and this special menace demands special measures. We need action; it is not the moment for passivity or indifference.

DISCUSSION

GODIAS J. DROLET

Statistician, Research Service, New York Tuberculosis and Health Association, New York, N. Y.

THE Chicago tuberculosis authorities and Dr. Goldberg should be congratulated upon their open-mindedness in placing before the Vital Statistics Section of the American Public Health Association their Mexican tuberculosis survey results before their publication.

Dr. Goldberg would modify the statement of Jefferson that "all men are created equal." I agree with him that undoubtedly all men are not *now* created or born equal—but human flesh was originally and it may even be said that under similar *previous* and *present* environments it is being created equal. Tuberculosis susceptibility or resistance can, under similar circumstances, be developed equally.

Personally, I do not like the phrase about the Mexican that he is of "another race, which has no demand upon us." We stripped the Mexican of California, Arizona, New Mexico, and of Texas. Now, when he is willing to labor for us, we would begrudge him life itself. Knowing the inherent devotion of Dr. Goldberg to the sick, I do not think he really intends all the implications of such a statement.

The Mexican is indeed a composite Indian-Negro-Spaniard, descendant of races all accustomed to sunlight and fresh air. He must, indeed, suffer terribly in the dusty, cloudy, choking cities, but may it not be, just as the negro has been found relatively immune and more resistant to hookworm infection and to certain digestive disturbances, that the old Indian stock does bring along favorable genes against the vagaries of American climate—with possible beneficial qualities against the high pneumonia incidence now prevailing in the implanted human stock in America —and some better body growth capacities, upon native food (corn, tomatoes, potatoes), than Europe's transplanted flowers.

The best contribution of Dr. Goldberg's paper is, of course, the figures of the Mexican survey in Chicago, and the results of the actual examination of 1,197 individuals of that group.

From their findings, the Chicago authorities compute a tuberculosis morbidity rate of 20.05 per 1,000 examined, and say that "in Mexicans it is 10 times greater than in the general population," basing this upon the fact that 7,798 cases of tuberculosis were reported in that city last year, and therefore that they had already figured a general tuberculosis morbidity of 2.51. But in the above, first of all, the ratio of 2.51 to 20.05 is not 10 to 1, but only 8 to 1; second, there is a statistical error in attempting to compare the two on the same basis. The Chicago morbidity rate of 2.51 is for only *new* cases reported in the city during the year, and not for the total old and new in the entire city on a given date (which is usually at least twice as high a number), whereas the Mexican figures are for the total tuberculous in their group on a given date, including both new ones of recent accession and perhaps, as in any other group, the old ones of a previous year. Furthermore, the Mexican figures are based upon a presumably thorough examination and complete reporting of all their cases, whereas the general Chicago figures are of no such careful and complete origin. In my opinion, therefore, I would first say it is probable that the total tuberculosis incidence rate of Chicago on a given date is perhaps 5 per 1,000 population, and that the Mexican morbidity ratio to that of the general

population is nearer being under 4 to 1. This necessary correction, however, certainly does not break down the seriousness of the figures of the incidence of tuberculosis among the Mexicans in that city, though it may reduce their relative importance.

Considering the mortality rate among Mexicans of 970 per 100,000 we have, however, in Dr. Goldberg's figures an undoubted evidence of the seriousness of the situation in this group.

The necessity for finding remedies against tuberculosis brought in by new racial groups is well expressed by Dr. Goldberg. Personally, however, I question whether merely a thorough physical examination of incoming Mexican immigrants will be the solution. That type of examination does not sort out susceptibles; it would not exclude a husky, handsome, strongly built Irishman, or a blue-eyed Scandinavian arrival, and yet both, under actual test of city life, may break down most piteously with tuberculosis. Shall it be a tuberculin test? shall it be a careful history taking? shall it be but a general realization of the disease susceptibilities of certain groups, and a particular consideration of the specific dangers they will encounter? or shall it be a more definite supervision in cities of such groups? It is hard to say what is the solution, but all must be thought of.

Chicago should be congratulated upon the earnestness and ability with which their tuberculosis authorities are facing their responsibilities. Dr. Goldberg has helped us to appreciate once more that the tuberculosis problem in our cities reflects a composite picture, deeply affected by the various racial groups already within, or coming into the community, and that he offers us a practical example on how to face it by study and intelligent attention.

Child-Welfare Work of the Sickness Insurance Funds in Germany

THE sickness-insurance funds of Germany, which are a part of the compulsory social insurance system of that country, have been devoting particular attention to child welfare work in recent years.

Considerably more than half of the sickness-insurance funds have extended their sick benefits to the children of insured persons. Preventive work with children has been emphasized, and as part of this work provision has been made for dental treatment and gymnasiums, ultra-violet ray clinics, clinics for diseases of the throat and nose, etc. Moreover, in recent years the sick funds are also making greater provision for treatment of children of insured persons in recuperation homes and sanitariums.—*Zentralbl. f. Jugendrecht und Jugendwohlfahrt,* Berlin, Sept., 1928, p. 158.

Health Demonstrations*

GEORGE C. RUHLAND, M. D., FELLOW A. P. H. A.

Health Commissioner, Syracuse, N. Y.

WITHIN the past ten years or so there have come into existence, especially in the United States and Canada, undertakings of a specialized kind that are commonly referred to as "health demonstrations." They are all more or less of the kind for which the well-known demonstration at Framingham may be taken as the prototype.

Among these demonstrations may be listed: the four receiving aid from the Commonwealth Fund,[1] at Fargo, N. D., Athens and Clark County, Ga., Rutherford County, Tenn., and Salem, Marion County, Ore.; those helped by the Milbank Memorial Fund[2] in Cattaraugus County, N. Y., Syracuse, N. Y., and the Bellevue-Yorkville District of New York, N. Y.; the demonstration in Mansfield, Richland County, O.,[3] toward which the American Child Health Association and the Red Cross gave support jointly; the demonstration in Montreal[4]; the work in the East Harlem Health Center, New York, N. Y.[5]; and the special tuberculosis study in the Dubois Health Center, Detroit, Mich.[6]

It seems entirely proper to mention, in this connection, also the contributions by the Rockefeller Foundation[7] to the budgets of rural health service in 207 counties in 24 states, as well as the coöperation of the U. S. Public Health Service[8] in demonstration projects in 86 counties, or districts comparable to counties, in 18 states.

This list of health demonstrations might be still further extended, without counting similar undertakings in foreign countries, by including cities in this country in which, through assistance from such agencies as the Commonwealth Fund, Rockefeller Foundation, The American Child Health Association, Metropolitan Life Insurance Company, and other sources, demonstrations in mental hygiene, child guidance and other specialized health problems have been undertaken.

As most of these undertakings have been operating for only a brief number of years, it would be unfair to pass judgment at this time on their value. Nevertheless, it seems permissible to venture some general observations on the subject of health demonstrations.

---

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

What has brought them into being at this time? What is the thought underlying the promotion of health demonstrations? On what plans are they undertaken? and are these sound? What response is there to them? Are they worth while? These are some questions that might properly be asked, and for which an answer seems, at least in part, available.

What has brought about the development of health demonstrations at this time? As an answer to this question, the following, quoted from the introduction of a report[9] by The American Child Health Association on 5 years of its activities, may conveniently serve.

> When, however, in 1920 the war draft figures were published, they gave a picture of conditions that startled us out of our complacency. They showed that about 70 per cent of all the men of draft age were physically below normal. At the other end of the line, we were told that 80 per cent of our children were born perfect. That meant in this great country of ours, with its comparative freedom from poverty, its ample space, abundant food supply and general excellence of climate, where, if anywhere in the world, children should have a right to health, that in the arc between birth and maturity were accumulating conditions which robbed the youth of this nation of their full heritage of health and happiness. Here in our own country was a job that challenged us.

This is the reason given by the President of The American Child Health Association for the formation of that organization, and this undoubtedly is the reason that has quickened the formation of the various undertakings of health demonstrations throughout the length and breadth of this country as well as elsewhere.

The stimulating or accelerating factor in the development of health demonstrations does not primarily seem to have been an appreciation of the economic value of human life. That appeal had already been ably made, in the *Report on National Vitality*, prepared by Professor Irving Fisher for the National Conservation Commission in 1909,[10] but had not been productive of any undertakings in the field of health conservation comparable with the present-day health demonstration movement.

It was obviously the emotional appeal of impressive statistics taken from the report of the Draft Board against the background of the dramatic setting of the recent war which essentially hastened the development of the special health activities known as "health demonstrations" within recent years.

It should be clearly understood, however, that in suggesting the emotional appeal as influencing the development of health demonstrations, this is to apply only to the acceleration of this movement, and not to the underlying motive which prompted their undertaking.

The justification for health demonstrations rests fortunately on a far firmer basis.

The foundation for health demonstrations is, of course, the same as for all other health work; namely, a recognition of the economic value of human life; an appreciation of the costliness, and therefore the undesirability of sickness; the right of society to protect itself against sickness, and its hurtful effects; an understanding of the fact that public health is made up of individual health, and an acceptance of practices and procedures tried and proved for the purpose of disease prevention and for the preservation and promotion of health.

There manifestly is in all of this nothing that marks or differentiates the work of health departments from that of health demonstrations, nor does it appear from all that is available on the work of health demonstrations that these are intended to function in any way other than in conformity with these fundamentals. There is nothing experimental about health demonstrations except in the technic of establishing modern health procedure in a given community, and in so far as the relationship of humans to one another is always experimental.

The purpose of health demonstrations and the reason for their being appear to be essentially this—an effort by demonstration to advance the education of the public in matters that have been tried and found good in disease prevention and health promotion.

The movement that has stimulated and is aiding health demonstrations recognizes that the chief difficulty in the way of realizing the possibilities in public health improvement arises from the fact that the public has not yet caught up in understanding and practice with the knowledge and facts which science or experience has obtained for us.[11]

If appropriations for health work are not yet on a par with those for other departments of public service, it is because we have not yet made it sufficiently clear to the public that health is quite as important as, for example, education, or that we have not made clear the methods by means of which we can secure these benefits.

If preventable diseases still persist so largely it is because we have failed to impress the public sufficiently with the importance of their prevention or have failed to point out a practical procedure to secure their prevention.

If the cost of hospitals and institutions for the care of chronics and incurables is still mounting as a public burden, it is because we have not yet succeeded in getting sufficient understanding of the importance of: child guidance and mental hygiene, periodic health examinations (Dr. Glendening, notwithstanding),[12] and early, persistent treatment.

Health demonstrations have come into existence in response to the obvious necessity that the public must be further educated in the possibilities of preventive medicine and the fundamentals of personal hy-

giene; and that such education can best be accomplished by demonstrations; and because of the equally patent fact that health departments are largely without the means to undertake such educational work without financial assistance.

Funds for the demonstrations are essentially from private sources. In all instances financial assistance is qualified; that is to say, certain stipulations must be met by the community in which the demonstration is undertaken. Thus the demonstration work in rural sanitation, for which federal aid is requested through the U. S. Public Health Service, will not be granted unless the community agrees to pay at least one-half of the expense.[13] Aid from the Rockefeller Foundation "is conditioned upon substantial contributions from other sources," and is further qualified in that it is only for demonstration of innovation and improvement. The fund withdraws entirely from a project as soon as it has become self-directing and self-supporting.[14]

The same policies govern contributions from the Commonwealth Fund, the Milbank Memorial Fund, the Metropolitan Life Insurance Company, the American Child Health Association, and other agencies. In all instances development of service by and through local official agency is sought, so that the activities developed may become permanent.[15, 2, 16]

Initiation and support of demonstrations are further conditioned upon invitation by proper local official authorities and community representatives, and the local medical profession; and qualified by geographical location, local needs and facilities and assurance of coöperation.

The plans for different demonstrations have varied, according to the special interests of the contributing agency. Thus the demonstrations receiving aid from The American Child Health Association and the Commonwealth Fund center upon child welfare; others, like those in Framingham, Montreal, and Detroit, center upon tuberculosis, etc. The demonstrations receiving grants from The Milbank Memorial Fund follow a general health program, as do the rural health demonstrations receiving help through the U. S. Public Health Service.

It is of interest to note that in all of the demonstration fields where the program was conceived primarily as a specialized service, the work sooner or later broadened into a more or less general health program.

It is of interest also to consider the experience in the various demonstration areas as to the time required for the accomplishment of work undertaken. For obvious reasons the contributing agency cannot commit itself to a program of support for an indeterminate length of time. The general plan followed stipulates that the community in

which the demonstration is carried on will, within a certain number of years, take over such service as appears essential to its needs, for which the contributing agency primarily has advanced the necessary money.

In Framingham the original plan called for a 3-year program. However, the demonstration was prolonged for 7 years. The demonstrations carried on through the coöperation of the Commonwealth Fund, as well as those aided by the Milbank Memorial Fund, are planned on a 5-year time limit. The latter agency has, however, at the invitation of the communities in which it assists, considered favorably the advisability of extending the time limit.

In the foregoing has been briefly sketched the growth of health demonstrations, especially in the United States; the underlying thought in their development; the general policies, plans and period of their operation. There remains the all-important question—Are they worth while? No final and conclusive answer can be made to this question at this time. However, the following points may be made from a study of the reports of the various demonstrations available thus far:

1. The purpose of these health demonstrations—to advance public health education by demonstration—is unquestionably good.

2. The plans and policies of the demonstrations—to work only where wanted; to work through and not on a community; to have the local community share in the financial responsibility of undertakings and to withdraw as soon as the local project has become self-supporting and self-directing—are likewise sound.

3. Time limitation for demonstrations, necessary from the viewpoint of the contributing agencies, has had a tendency to force the development of progress in some demonstration areas, creating difficulties in administration.

4. A fixed program with specialized objectives is an evident advantage for the initiation of health demonstration work. It seems important, however, to keep the program elastic so that it can be shaped to suit special local needs and interests. Sooner or later all demonstrations broaden out into a general health program.

5. Growth of demonstrations indicates public approval. The request to continue demonstrations beyond the originally stipulated time agreement is especially suggestive of this conclusion.

6. The cost of demonstrations does not appear excessive, and has not so far exceeded $2.00 per capita anywhere. Whether this is adequate or not the future must determine. The public appears willing to pay for the service, and budgets for health work have been generally doubled over their original appropriation within the time of the demonstration.

7. The demonstrations have in all instances brought about an extension of health service which, with few exceptions, has been maintained in full or in part after the withdrawal of the contributing agency.

8. The educational effect of demonstrations can obviously never be fully measured. In many instances it has, however, resulted in such tangible evidence as the improvement of water supplies, sewage disposal, proper milk and food control, building of schools, noticeable changes in the dietetic habits of communities, the

formation of health clubs, health conferences and other measurable services in standard public health procedure.

9. The experience with preventable disease in various demonstration districts has shown quite general improvement over pre-demonstration periods. In some instances results appear quite striking. Obviously these records must be treated conservatively.

It would be overlooking a material point in the experience of health demonstrations if nothing were said concerning certain difficulties that have been encountered in some demonstration areas.

It is rather disappointing that these difficulties should have arisen from within the ranks of the medical profession. Fortunately, however, it would appear that most of these difficulties can be cleared by getting over to the medical profession a better understanding of the purposes and methods of demonstrations. It is significant that where the profession is best informed, the work of the demonstrations has had its strongest endorsement and support.

The explanation of the difficulties encountered perhaps lies in the fact that the health demonstration movement has addressed itself too exclusively to the public, and has taken it too much for granted that the rank and file of the medical profession has kept pace with the trend of time, which also in the field of medicine is shifting from a purely curative practice to one which places emphasis more and more on prevention.

The practitioner of medicine must adjust himself to this inevitable change of which health demonstrations are merely an expression.

As an editorial in the *Journal of the American Medical Association* aptly puts it, "Today medicine—and particularly preventive medicine—is the property of all mankind. A progressive physician must be aware of his relations to the civic and economic problems of the community and the nation."

Modified Iodine-Pentoxide Method for Determination of Carbon Monoxide in Air and Blood*

MATHEW J. MARTINEK AND WILLIAM C. MARTI

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

THE danger from carbon monoxide poisoning in the large centers of population is becoming increasingly great. There is scarcely an industrial activity in which this gas is not encountered. The use of coal gas, water gas, and devices in which coal, oil, gas and gasoline are burned may be and often is attended by a danger to health when there is imperfect combustion or faulty ventilation. Automobiles also are contributing materially to air pollution, not only with irritating fumes but also with the invisible, colorless and odorless carbon monoxide gas.

The recognized effect upon health of small amounts of carbon monoxide continuously inhaled has brought an insistent demand for highly sensitive laboratory methods of quantitatively estimating this gas in concentrations as low as 0.1 part per 10,000 in air, and also in the blood of exposed persons. To meet this need our experiments were undertaken.

The first part of the experiment was devoted to altering and modifying existing methods and apparatus in order to obtain a method which would be accurate for very low concentrations. Methods such as the Orsat,[1] Blood Colorimetric,[2] Blood Spectroscopic,[3] Blood Pyrotannic,[4] and others were tried out but, although having many advantages, were eventually discarded as not fulfilling our requirements.

The method finally selected was the iodine-pentoxide method as modified by Teague,[5] which depends on the oxidation of carbon monoxide to carbon dioxide by iodine-pentoxide, and the accurate determination of the liberated iodine. It is based on the following reaction:

$$I_2O_5 + 5CO \rightarrow I_2 + 5CO_2$$

The report of the New York State Bridge and Tunnel Commission[6] was used as a basis for the construction of our apparatus. However, we introduced several modifications to improve the accuracy of the

* Read before the Laboratory Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

method and the simplicity of its operation. The apparatus as assembled (see Figure I) consists of a series of absorbing towers arranged in the following order: *C*, concentrated sulphuric acid, to remove a portion of the moisture; *E*, concentrated sulphuric acid heated to 150° C. by means of an oil bath *F*, which absorbs heavy hydrocarbons, most of the gasoline, and methane; *G*, cold, concentrated sulphuric acid, to catch any of the fumes liberated from *E*; *H*, *I* and *J*,

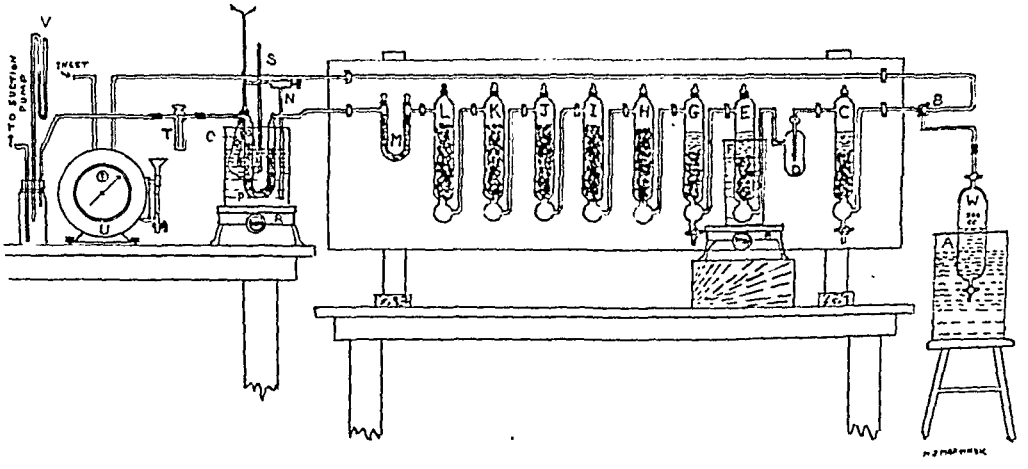

FIGURE I—APPARATUS FOR AIR ANALYSIS

activated charcoal, which removes the last traces of unburned gasoline and hydrogen; then a series of moisture absorbents consisting respectively of: soda-lime *K*, solid potassium hydroxide *L*, and dehydrite *M* (a mixture of magnesium perchlorate and trihydrate). These absorption towers are connected to a hard glass U-tube *O*, containing iodine-pentoxide, and immersed in a bath of oil *P*, kept constantly at 150° C. by means of a thermostat *N*, and electric light *Q* connected in series. All the towers are mounted on an upright board for stability and economy of space.

The liberated iodine is finally absorbed in a specially constructed absorption bulb *T*, containing 5 c.c. of 10 per cent potassium iodide. This bulb is in turn connected to a standard meter *U*, which registers the volume of gas flowing through the apparatus, and finally to a manometer *V*, which indicates variation in pressure of the gases flowing through the apparatus. The gas is drawn through the apparatus by means of a Bunsen vacuum pump. The inlet of the apparatus consists of a 3-way stopcock *B*, which allows either ordinary air or the sample of air to be tested to be drawn through the apparatus. Heating of the oil baths is done by means of electric stoves *R*.

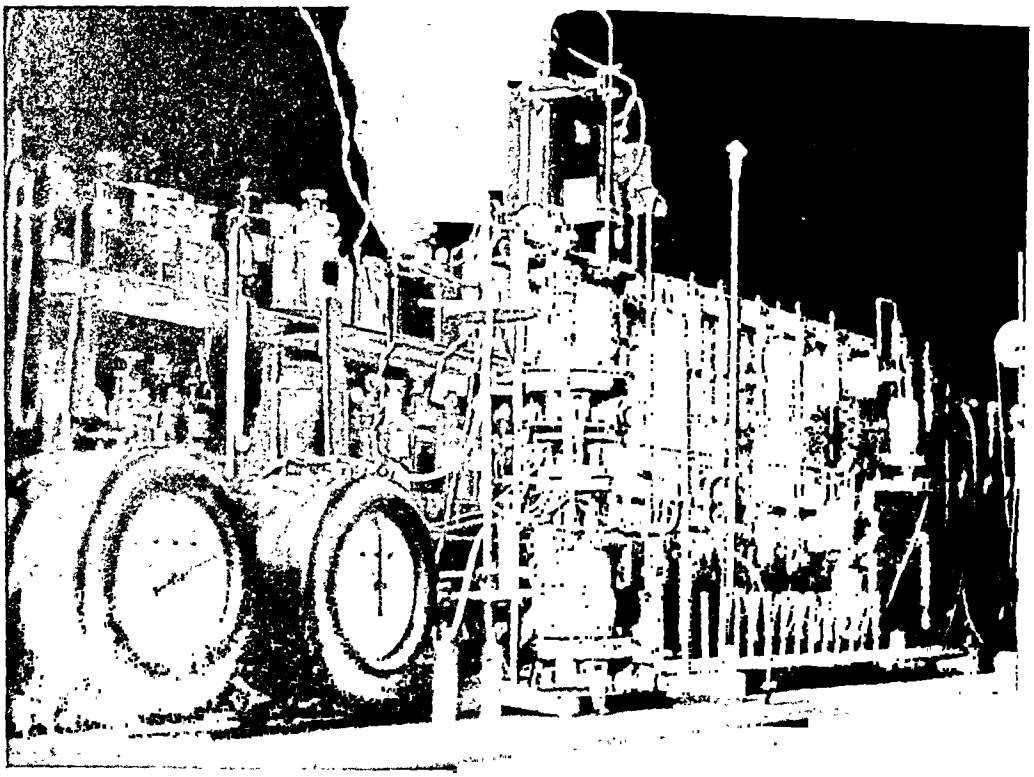
Before any test can be made, the iodine-pentoxide must be heated to 215° C. for several hours, to remove any free iodine or moisture.

This process is called "seasoning." We continue this "seasoning" until practically no iodine is liberated.

The sample of gas to be analyzed is passed into the apparatus from a 500 c.c. Thoerner gas bottle *W*, by displacement with saturated salt solution, and the apparatus is then washed with 3½ liters of air. The washing requires about 45 minutes. The liberated iodine is then titrated with N/200 sodium thiosulphate solution, using a microburette.

The apparatus was tested by running several hundred duplicate samples containing known amounts of carbon monoxide, and the following are average results of a typical series of varying concentrations:

No. of Determinations	Carbon Monoxide (in parts per 10,000)		Deviation of Determined Findings from Computed parts per 10,000
	Computed	Determined	
7	9.75	9.67	−0.08
7	4.90	4.84	−0.06
5	1.00	0.95	−0.05
9	0.50	0.44	−0.06
7	0.20	0.15	−0.05



The percentage of error increased with the increase in dilution, although the average error was 0.06 parts per 10,000 for all concentrations. In the great majority of the determinations (95 per cent) the error was under 0.10 parts per 10,000, which we regard as the limit of accuracy of the method.

To determine the effect of gasoline, which is always present in automobile exhaust gases, in the determination of carbon monoxide with the apparatus, about 100 prepared samples were tested. Quantities of gasoline, ranging from 0.1 c.c. to 1 c.c., were added to the 500 c.c. sampling bottle containing the carbon monoxide, before the sample was passed through the apparatus. The following are the average results of a typical series of such analyses:

No. of Determinations	Carbon Monoxide (in parts per 10,000)		Deviation of Determined from Computed parts per 10,000
	Computed	Determined	
3	9.58	9.69	+0.11
3	0.94	0.95	+0.01

The results showed that gasoline in concentrations generally found in exhaust gases has no material effect on the determination of carbon monoxide with the apparatus. Unsaturated hydrocarbons were also effectively absorbed, as well as hydrogen in the very small amounts usually found in exhaust gases.

The following features of the apparatus as modified by us, both in construction and operation, should be noted:

DUPLICATE SET-UP FOR ROUTINE WORK

1. All connections on the apparatus are so made that the gases at no time come in contact with rubber. The various absorption bulbs are arranged in series, and those requiring the least replacement of absorbing material contain solid reagents, while those requiring frequent replacement contain liquid reagents, the latter bulbs being emptied by means of stopcocks in the lower end. This feature obviates dismantling of the apparatus whenever it becomes necessary to renew the reagents.

2. The absorption towers and attachments are mounted on an upright board, thus occupying a minimum of space. The main portion of the apparatus can also be moved easily without disturbing the connections.

3. By the introduction of the gas meters, we were able to insure equal volume of flow through the apparatus at all times, thus avoiding any great variations in the blank determinations.

4. To avoid discrepancies in results which may occur from changes in the temperature of the oilbath heating the iodine-pentoxide tubes, a thermo-regulator connected in series with an electric light bulb was placed in the bath.

5. Our absorption towers were designed or chosen with the purpose of obtaining the maximum absorption with the least amount of head to overcome.

6. "Dehydrite" (magnesium perchlorate, trihydrate—Smith) was found superior to phosphorus pentoxide as a drying agent, as the former does not clog and cause back pressure in the apparatus.

7. The absorption tower, containing the potassium iodide solution, was so constructed that a trap was unnecessary in case of back pressure.

8. The use of a micro-burette, having a capacity of 5 c.c. and accurately calibrated to 0.01 c.c., improves the accuracy of the method. In order to make

the delivery tip sufficiently small and the delivery at the same time accurate, a platinum hypodermic needle was ground to fit the tip of the burette, and the number of drops equivalent to 1.0 c.c. was accurately determined.

After the perfection of the above mentioned apparatus, we experimented on the determination of carbon monoxide in the blood of persons exposed to small concentrations of the gas, and devised the accessory apparatus shown in Figure II for that purpose.

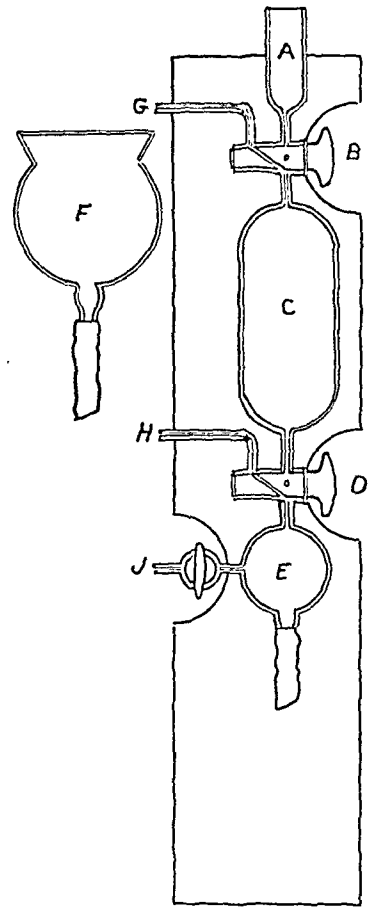


FIGURE II—ATTACHMENT FOR BLOOD ANALYSIS

The apparatus for analysis of blood is operated as follows: It is entirely filled, to stopcock *B*, with mercury by raising leveling bulb *F*, and opening stopcocks *B* and *D* straightway, keeping stopcock *J* closed. Stopcock *B* is then closed, and *F* lowered to produce a vacuum. Three c.c. of the oxalated blood under examination are pipetted into funnel *A* and are then carefully drawn into chamber *C* by slowly opening stopcock *B*. This is followed by 10 c.c. of boiled, distilled water to rinse the funnel, and then by 10 c.c. of a reagent,[7] made up of the ingredients given below.

Potassium ferricyanide	8.0 gm.
c.p. Lactic acid	4.0 c.c.
Saponin	3.0 gm.
Caprylic alcohol	3.0 c.c.
Water, Qs.	1,000.0 c.c.

This reagent liberates the gases from the blood very rapidly under reduced pressure. The apparatus is then shaken for 10 minutes by means of a motor attachment similar to that used with the Van Slyke apparatus.

Leveling bulb *F* is then lowered in order to cause all liquids in *C* to enter *E*, and stopcock *D* is then closed, care being taken that stopcock *B* is tightly closed. The liquids over the mercury are then ejected from the apparatus through *H* by turning stopcock *D* and raising *F* carefully, thus leaving *E* entirely filled with mercury. Then mercury is lowered in *E* until the level is below *J*. The connection *G* is next attached to the inlet of the modified carbon monoxide apparatus first described (Figure I), and *J* is connected to the outlet end

of the meter. The gases liberated from the blood, and held in chamber *C*, are now drawn through the apparatus by opening first stopcock *J*, then stopcock *D* straightway, and lastly stopcock *B* through *G*. The apparatus is washed out thoroughly with air, and a blank on a like volume of air is run.

By means of this apparatus we were able to determine carbon monoxide in blood concentrations as low as 0.003 c.c. of the gas per 3.0 c.c. of the blood, or a saturation of 0.5 per cent, which amount is well below the dosage producing physiological effects.

NOTE: The authors wish to acknowledge the valuable assistance of Fred O. Tonney, M.D., Director of Laboratories and Research, and J. J. Aeberly, Chief of Ventilation Bureau, Chicago Department of Health, in carrying out this work.

DISCUSSION

FRED O. TONNEY, M. D.

Director of Laboratories and Research, Department of Health, Chicago, Ill.

AS civilization progresses, new material advances give rise to new health hazards, which are the consequence of changes in living conditions and environment. So it is with the unprecedented development of automobile transportation.

Health officers must be ever on the alert not only to meet the hazards of the present, but also to anticipate the hazards of the future. From the data of this paper and its companion paper read in the Engineering Section, embodying the results of a survey of street air in Chicago,[1] it becomes apparent that in the growing use of the gasoline motor we have to deal not only with a well known though perhaps minor hazard to life from carbon monoxide, but also with an ever impending and at times actual hazard to health, which is of even greater concern to us from the standpoint of numbers affected.

For this timely information on the public health dangers of carbon monoxide in street air, we are indebted primarily to the foresight of chemists who, within a few years, have taken the cruder analytical methods and refined them to an almost unbelievable degree of sensitiveness and precision. They now tell us the carbon monoxide content of air with accuracy down to less than 0.1 part per 10,000—a thing that appeared impossible a few years ago. To the engineers we are indebted for the practical application of these painstakingly evolved chemical methods.

Such problems as the aggregation of tall buildings affecting air movement, the ventilation of the lower levels of doubledecked streets, the peak of air pollution by rush hour motor traffic and, as a consequence of these, the necessity of safeguarding the health of the multitude of workers who must breathe this air hour after hour, day after day, and month after month—all these new problems, like the other older health problems, are in a fair way to be solved when they are once fully and thoughtfully recognized.

This particular problem of congested community life will be solved as others have been solved, not by regression, but by progression. It is unthinkable that, for health's sake, we may some day have to dispense with or restrict the use of so useful a tool as the gasoline automobile, for the sole reason that its combustion of fuel is incomplete and imperfect. The logical forward step toward the solution is to find ways of insuring complete combustion in the gasoline motor and to apply them as fully as possible, with the coördinated objectives of safeguarding health and conserving fuel.

The perfection of mechanical design, the use of chemical catalytic agents to accelerate combustion and the possible means to dispose of products of incomplete combustion, are some of the subjects for intensive study. I feel that we of the Laboratory and Engineering Sections are indeed fortunate in having had such an opportunity as these papers present to secure definite information on the actual conditions as they exist today and on the present and potential health hazards inherent in this modern transportation development.

HYGIENE IN MEDICAL SCHOOLS

EVEN if it were not so freely admitted, the discussions which have gone on, and are still taking place, over medical education and the arrangement of the curriculum would prove that there is something wrong in our present methods of teaching. There are few, perhaps none, who are entirely satisfied with the present state of affairs, and there is an earnest effort to correct obvious faults. The whole matter may be summed up by saying that medicine has become such an enormous subject, while life is so urgent and so short, that it is impossible to give the ideal amount of time for proper education in the profession. New discoveries are piling up daily. The professor in whose branch a particular discovery lies must add it to the subjects taught, although his time is already insufficient for the matter in hand. Specialism is rampant, and each specialty demands its particular school, or at least a course. The difficulties are obvious. Further lengthening of the time required for the degree of Doctor of Medicine is almost out of the question. The obvious task is to apportion properly the time among the necessary and fundamental subjects.

Some schools are trying to meet the difficulty by giving fewer hours to required subjects and allowing more time for electives. While this has certain advantages, the wisdom of too great liberality is extremely doubtful. Medicine has become a business rather than a profession. Many of the high ideals of the fathers of medicine have gone down before the fire of commercialism, and the average student is not in a position to select judiciously his elective subjects. He will be swayed by the success of certain older men, including perhaps his father, or by the popularity of one or the other professor. The experience of laboratory men shows the difficulty of obtaining graduates in medicine for laboratory work. The emoluments of practice are so much greater

than can be hoped for from laboratory work that students are turning away from the latter.

In a journal like ours, we do not propose to discuss the entire medical curriculum. We are concerned in preventive medicine and hygiene. The Association of American Medical Colleges requires 54 hours as a minimum in these subjects. The average of 17 leading colleges is 47 hours. A recent schedule[1] devotes only 12 hours to hygiene and sanitation, an hour percentage of 0.4 as compared to 3 to 4 recommended by the Association of American Medical Colleges. It is explained that this small allotment of time is due to the inclusion of most of the instruction in preventive medicine in the schedule of the medical department. The same schedule drops bacteriology to 88 hours. The makers of this schedule are said to believe "that clinical medicine should be the backbone of the curriculum," therefore more than one-third of the required hours are given to that branch, which includes psychiatry, pediatrics, etc.

It has often been pointed out that public health is a profession requiring special training. Without a desire to criticise, it may be said that the average medical teacher has not had special training in bacteriology, preventive medicine, hygiene or sanitation, and is not in a position to teach these subjects to students. It is perfectly natural that the clinician should be interested in clinical medicine, with the various and rapidly multiplying methods of diagnosis and treatment. It is perfectly true that such a professor, while teaching typhoid fever —the example used in the article referred to—may tell how to disinfect the stools and urine, and may give the common sources of infection and a glimpse at the epidemiology of the disease; but it is extremely unlikely that he will treat the subject adequately, for lack of time if for no other reason, and his interests lie chiefly in the clinical side of the disease.

It is perfectly obvious that the good clinician is practicing preventive medicine, whether or not he recognizes it. With each cured case, a focus of infection is destroyed. This should never be lost sight of by those who go perhaps too much to extremes in pushing hygiene. On the other hand, one cannot imagine the average clinical professor teaching much about bacteriology, vital statistics, the physics of ventilation, lighting and heating, the purification of water supplies or the many other subjects which come properly under the head of hygiene. It is, of course, possible to develop a new type of medical teacher. The evolution is going on at present, but it is a fact that these subjects are not being generally or thoroughly taught by professors of medicine.

Anyone who reviews the papers presented before the National Board of Medical Examiners is necessarily convinced of the fact that the teaching of hygiene is extremely deficient. Students from some of our leading universities do not even know the meaning of maritime quarantine. They cannot give the insect-borne diseases met with in the United States, much less tell the difference between Aëdes aegypti and Anopheles. No one who has been a teacher will judge teachers too severely by the showing of students, but surely fundamental facts of importance should stick if properly implanted.

Instead of decreasing the number of hours given to preventive medicine and its various branches, they should be increased, and the importance of prevention should be magnified rather than subordinated to treatment and cure. Recognizing fully the wonderful advances in medicine and surgery, and the appeal which the relief of suffering and restoration to health always carry, it can still be said that prevention is more important than cure. Too long has medicine been regarded as the "healing art." It is time for a readjustment of the emphasis. The medical schools which fail to read the signs of the times will find their graduates more and more replaced by those of non-medical schools which lay stress on biology, sanitary engineering and kindred subjects.

ACCIDENTS

PREVENTIVE medicine has been concerned too exclusively with the prevention of disease, the great majority of its devotees still regarding that function as the chief, if not the only province of their profession. Some of the old dictionaries had in their definition of medicine "the remedying, as far as possible, the results of accident and violence." The speed of modern life has forced us to recognize the prevention of accidents as a part of our calling, though a casual survey of books on hygiene and preventive medicine indicates that only those interested in industrial hygiene have given the subject the attention which it deserves.

The 1928 report of the National Safety Council[1] arrests one's attention. During 1927, more than 95,000 deaths occurred by accident. If the same rate of increase holds for 1928, approximately 100,000 lives will have been lost. While the year showed a low general death rate, no improvement for accidents is evident. From 1911 to 1928, there was a total decrease in the death rate from accidents of

7.2 per cent, all of which, however, occurred prior to 1921, since which year the death rate has steadily increased. The actual number of deaths per year has increased 20 per cent. The most striking item is that deaths from automobile accidents have increased 1050 per cent during the same period. It is pleasing to note the great improvement in deaths from railway and street railway accidents—37 per cent in one case, and 44 per cent in the other. As might be expected, a large number of automobile accidents occur among children, most of them in the 5–9 year period. This rate is exceeded only in the longer 15–24 year period, by approximately 3 per cent. Defects in the vehicle, such as poor brakes, improper lighting, etc., played a comparatively small part in the total number of accidents, there being only 4,969 cases reported in approximately 200,000 vehicles. Intoxication and physical defects were reported in 3,163 cases, 90 per cent of these being the result of intoxication. As far as the responsibility of the driver of the car goes, the greatest number of accidents occurred through violation of the rules of right of way. Excessive speed, driving on the wrong side of the road, failing to signal and cutting in, come next in order as given. As far as pedestrians injured are concerned, crossing at intersections without a signal was the chief cause of accidents, crossing between intersections coming next, and playing in the street third.

A more recent report from the City of New York,[2] while not so detailed in character, shows that highway accidents lead as the cause of violent deaths—1,306 out of 5,902.

The figures taken from these two reports have been selected because, for the most part, they represent the more easily preventable causes of accidents. The railroads and street car lines have adopted very widely the "Safety First" slogan. It is recognized that the great increase in automobile traffic has had a marked influence in decreasing the number of passengers on railways and street cars, especially for the short hauls, but there is little doubt that care of equipment and instructions to operatives have also played a part. It seems time for those interested in hygiene and public health to take a more active part in the education of the public in the prevention of accidents, and for the influence of the vast body of health workers to be exercised, not only for the making of laws, but for the provision of officers to enforce such laws.

NOISE

WE live in a world which is noisy and daily becoming noisier. Mechanical inventions of every kind are replacing hand labor, and most of them produce noises of varying degrees of intensity. Even the air is now inhabited by planes. The speed of the times requires work both at night and on Sundays.

With the exception of hospitals and schools and the so-called quiet zones, the average person has probably accepted these new noises as inevitable. During the past two years the matter of noise has gotten into the medical journals of several countries. The physician interested in the treatment of insane or neurotic individuals is perhaps more concerned than the average doctor, though the good effects of rest and sleep are well recognized in the treatment of all diseases.

In England the matter has recently been brought to a focus by a memorandum submitted to the Minister of Health by the British Medical Association.[1] While it is particularly desirable that the usual hours of sleep—say from 10 p.m. to 6 a.m.—should be kept quiet, it is obvious that many persons work at night and rest during the day. Healthy persons seem capable of adapting themselves to noises, though this costs something in the amount of energy which must necessarily be expended in inhibiting the undesirable stimuli. Where a noise is rhythmic and uniform in quality, pitch and intensity, the average person apparently bears it with little injury, but noises which are irregular in any of these qualities do serious injury.

No argument is needed to emphasize the importance of rest and quiet sleep. Health can be maintained only when these can be obtained. Those who are sick need all their strength for recovery. Neither the sick nor the well can afford to have their necessary rest disturbed, especially where the noises are of such an unnecessary and aggravating character as to produce emotions of reaction such as anger and irritation. In approximately 75 per cent of cases of mental breakdown, loss of sleep is either a symptom, or causes an aggravation of the basic difficulty, and, on the other hand, production of sleep is recognized as a means of prevention and even cure.[2]

Among the disturbing factors which stand out prominently are the horns of automobiles, motorcycles, exhausts without mufflers, trucks without pneumatic tires—especially those handling milk cans—engines blowing off steam, cars with flat wheels, and in towns, street cars with flat wheels and loose trucks. Conditions differ according to the locality, but everyone will recognize some of these noises wherever he may be.

Those who are "nervous" are doubtless prone to exaggerate the

intensity and the bad effects of noises, but there are probably few people, even in the smaller towns or along the highways of the country, who will not admit the unnecessary disturbances both during the hours normally allotted to rest and those devoted to labor.

The Minister of Health, who is a layman, gave a sympathetic hearing to the joint deputation from the British Medical Association and the People's League of Health, pointing out, however, that some definition of what constituted noise must be agreed upon, and suggesting further that studies should be made in factories, such as are already being carried out by the Industrial Fatigue Research Board. People certainly vary tremendously in their reaction to stimuli of various sorts. One must remember the reply of the artillery officer at a concert who was asked if he was fond of music. His reply was, "Yes, I like noise of any kind."

ASSOCIATION NEWS

HEALTH SURVEY OF HONOLULU

The Committee on Administrative Practice of the A. P. H. A. has been asked to make a survey of public health activities in the City and County of Honolulu. This study, which is being sponsored by the United Welfare Fund of Honolulu, has the endorsement of the U. S. Public Health Service, the local board of health, the medical profession, hospitals of the city, the local chamber of commerce, and the most important voluntary agencies engaged in public health and welfare work. A special survey committee with wide representation has been appointed and is already actively engaged in gathering information and data which will be of assistance to the surveyor. Prof. Ira V. Hiscock will carry on the field work for the Committee on Administrative Practice, and will leave for Honolulu the latter part of May. Prof. Hiscock will have the benefit of consultant service from experts on certain phases of health work which are included in the survey.

DEATH OF MR. ROSSITER

William Sydney Rossiter, for many years President of the Rumford Press, Concord, N. H., died January 23, at his home, after an illness of a few days' duration.

Mr. Rossiter published the JOURNAL for several years and took an interest in its development even after it had been transferred to another publishing house. He was an ex-president of the American Statistical Association.

MAURICE M. SEYMOUR DIES

The Association announces with regret the death of Maurice McDonald Seymour, M.D.C.M., D.P.H., LL.D., formerly Deputy Minister of Health of the Province of Saskatchewan and a vice-president of the American Public Health Association. Dr. Seymour was president of the Conference of State and Provincial Health Authorities of North America in 1926 and was active in public health work in Canada for more than 20 years.

The following item has been prepared for the readers of the JOURNAL by F. C. Middleton, M.D., Acting Deputy Minister of Health of Saskatchewan:

Dr. Seymour was automatically superannuated in November, 1927, in accordance with the provisions of the Superannuation Act of Saskatchewan. However, the Government requested him to remain as Advisor to the Government on Public Health matters, there being just at that time several matters of importance to be dealt with by the department, one of which was a request made by the United Farmers' Organization of the Province that a travelling diagnostic clinic be established under the auspices of the department. It was then also that the time was considered ripe for introducing the full-time health district system into Saskatchewan, and Dr. Seymour had been promoting this scheme for the past few months previous to his death. His death, which was due to acute indigestion and chronic myocarditis, was very sudden, as he was sick only twenty-four hours. He had been in the office on Tuesday and passed away on Thursday morning, January 17. Dr. Seymour was an ardent worker and the fruits of his labors will be long felt not only in this province but throughout the Dominion and North America.

MICHIGAN PUBLIC HEALTH WORKERS MEET FOR EIGHTH YEAR

The Eighth Annual Public Health Conference of Michigan was held at Lansing, Mich., January 9–11, under direction of the Michigan State Department of Health and the Michigan Public Health Association with a registration of 286.

The following officers were elected:

President, Carl E. Buck, Dr.P.H.; *Vice-President,* Annette M. Fox, R.N.; *Secretary-Treasurer,* W. J. V. Deacon, M.D.; *Board of Directors,* Prof. John Sundwall, Don M. Griswold, M.D., Theodore Werle, W. D. Henderson, M.D., Louis Dorpat, M.D., and Mrs. J. K. Pettengill.

Guy L. Kiefer, M.D., was elected representative on the Governing Council of the A. P. H. A.

James W. Wallace, M.D., Associate Field Director for the Committee on Administrative Practice, A. P. H. A., represented the Association and addressed the conference.

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION OFFICERS

At the annual meeting of the Southern California Public Health Association held January 30, in Los Angeles, Calif., the following officers were elected for the year: *President,* Warren F. Fox, M.D., Health Officer, Pasadena; *First Vice-President,* W. B. Wells, M.D., Health Officer, Riverside County; *Second Vice-President,* A. M. Lesem, M.D., Health Officer, San Diego; *Secretary-Treasurer,* C. W. Arthur, City Bacteriologist, Pasadena; *Executive Committee,* Warren F. Fox, M.D., Health Officer, Pasadena; J. L. Pomeroy, M.D., County Health Officer, Los Angeles; C. W. Arthur, City Bacteriologist, Pasadena; Sven Lokrantz, M.D., Medical Director, Los Angeles City Schools, Los Angeles; H. A. Young, Chief Sanitary Inspector, County Health Department, Los Angeles; L. Simpson, R.N., Director of Nurses, County Health Department, Los Angeles; W. T. Knowlton, Sanitary Engineer, Los Angeles; G. E. McDonald, M.D., Health Officer, Long Beach; K. H. Sutherland, M.D., Health Officer, Orange County.

REPORT OF THE COMMITTEE ON THE STATUS OF MATERNAL AND INFANT MORTALITY

Anyone wishing to obtain the report of the Committee on the Status of Maternal and Infant Mortality of the Child Hygiene Section of the American Public Health Association may borrow the original report from the Association. The complete report has not been published in any of the journals because of the large amount of statistical material contained therein.

DEATH OF DR. WILLIAM H. DAVIS

William H. Davis, M.D., Chief Statistician for Vital Statistics in the Bureau of the Census, who died on January 8, was an outstanding figure in the field of vital statistics. He was a graduate of Harvard University and of the Harvard Medical School. After studying in Europe, he decided to devote himself to vital statistics work, and became, in 1908, Deputy Health Commissioner and Vital Statistician of the City of Boston. In 1916, he was appointed to the position in the Bureau of the Census left vacant by Cressy L. Wilbur, M.D. He filled this position according to the best traditions left by his predecessors, Dr. Wilbur and William A. King, both truly great men. Due to Dr. Davis's work in the Bureau and his active connection with the world-wide movement for better vital statistics, he became one of the foremost authorities in his chosen profession.

In the Bureau of the Census, his energy was largely directed toward the completion of the registration areas for births and deaths; and second only to their sorrow at the loss of the man himself is the regret of his professional associates that Dr. Davis did not live to see the day (near at hand) when success will crown his long campaign for country-wide registration of these vital data. He enlisted in this campaign the active assistance of the American Public Health Association, which appointed its

Committee to Aid Completion of the Registration Area.

He was actively interested in the scientific classification of diseases for purposes of mortality and morbidity statistics. In this he was a recognized authority throughout the world. He was an active member of the Committee on Accuracy of Certified Causes of Death (Vital Statistics Section of the A. P. H. A.). This committee, largely through Dr. Davis's efforts, was instrumental in bringing about important improvements in the International List of Causes of Death. In 1920, he was one of the United States delegates to, and Vice Chairman of the International Conference, at Paris, for the revision of this classification. In 1927, he again went to Europe to consult with foreign nosologists concerning problems to be considered by the next International Conference on revision of the classification. In 1925, on invitation of the League of Nations, he joined a tour of medical statisticians, with the object of bringing about closer agreement in international statistical practice.

Dr. Davis was a prominent figure in the A. P. H. A. He was a Vice President in 1923, Chairman of the Vital Statistics Section in 1919–1920, and, year after year, served as chairman of important committees.

One outstanding contribution was the Bureau of the Census *Manual of Joint Causes of Death,* published in 1925. This gives the best method of disposing of one of the most troublesome phases of codifying causes of death. Dr. Davis deserves special credit, also, for his improvements in the Standard Certificates of Births and Deaths.

While with the Boston Health Department, he wrote two valuable pamphlets: *The Relation of the Foreign Population to the Mortality Rates for Boston* and *The Statistical Comparison of the Mortality of Breast-Fed and Bottle-Fed Infants.*

The Bureau of the Census mortality reports were improved in several respects while Dr. Davis was Chief Statistician. Especially noteworthy were his tables showing contributory as well as primary causes of death. During his administration, much valuable information was made public when it was of *current* interest. This was appreciated by public health workers and the press, which used Dr. Davis's announcements in news dispatches and editorials.

Personally, he was a modest, kind-hearted gentleman. The whole-hearted sympathy of all who knew him goes out to his widow and children. He was liked and respected by his colleagues, who recognized his zeal for his chosen profession and his fine, companionable personality.

EDITOR'S APOLOGY

Proof of the discussions on pp. 28–30 of the January, 1929, JOURNAL, following the article, "Mobilizing Mutual Benefit Associations for Health," was *not* submitted to the discussants before publication.

The statements were printed verbatim from the notes.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Conference on Influenza, January 10, 1929—The following is a report of one of the three committees of the Conference.*

REPORT OF COMMITTEE ON EPIDEMIOLOGY

The features which have distinguished influenza in its typical pandemic outbreaks, such as those of 1918 and 1889–90, are:

1. A great increase in the prevalence of illness of which the usual symptoms are: fever, of more or less sudden onset, of moderately high range and of only a few days' duration; aching of the body and limbs; inflammation of the upper respiratory passages, and marked prostration. In its manner of spread this disease has the characteristics of a highly contagious infection, transmitted directly from person to person.

2. Coincident increase in the prevalence of pneumonia, developing apparently as a complication of a certain proportion of the influenza cases.

3. A rise in the general mortality rate, due largely to increase in deaths certified as influenza or pneumonia. These deaths characteristically show an age distribution different from that of normal times, in that the proportion of young adults is increased.

4. In any given locality, the epidemic develops and runs its course rapidly, so that its duration, even in a large city, is a matter of not more than 5 to 10 weeks.

5. The tendency is to rapid and wide extension, different communities being attacked in such quick succession that the spread across a continent requires only a few weeks, and where the disease becomes pandemic it travels around the world within 3 to 6 months.

The epidemics which show the full development of all these features, including world-wide prevalence, are rather rare events, recurring at intervals which usually have exceeded 20 years. However, at much more frequent intervals we have minor epidemics, similar in general character, but differing from the typical picture in some respects, notably in lower prevalence, less severe clinical type, slighter effect on mortality, and less extensive area of spread. The exact relationship which these bear to true pandemic influenza is still a matter for investigation rather than fixed opinion; but the more distinct of the minor epidemics are generally accepted as true influenza of modified virulence and intensity. Since 1919 at least two such outbreaks have occurred in the United States, one in 1920 and one in 1926, with some more doubtful epidemics in other years.

The data available at this time for judging the nature, extent and severity of the present epidemic are: clinical accounts of the cases seen in communities already attacked; official morbidity reports, which are admittedly incomplete and uneven, but have nevertheless a certain significance; and, for the large cities listed in the *Weekly Health Index*, weekly reports of deaths from all causes, and from influenza and pneumonia.

All this evidence agrees in indicating the existence of a definite epidemic of influenza. It seems to have developed first in the vicinity of San Francisco, early in November. Since that time it has extended, with characteristic rapidity and in fairly regular sequence, until it has now become demonstrable in all sections of the United States except the northeastern states.

The epidemic is already on the decline in those western cities which were first affected; and has apparently reached its peak in some middle western cities, but in the east seems not yet to have reached

* Report of the Committee on Preventive Measures appeared in the JOURNAL for February, 1929, p. 205.

its full development. The effect on mortality has not approximated that caused by the pandemic of 1918, and has been less than in the epidemic of 1920, but more severe than at any time since the latter date.

For the statistical and epidemiological study of the epidemic we recommend:

1. That the U. S. Public Health Service continue and extend its activity in the collection and compilation of morbidity and mortality statistics, to afford both a current and a permanent record of the epidemic.

2. That the U. S. Public Health Service undertake special surveys of morbidity in a sufficient number of localities to give a more exact picture of the prevalence and epidemiology of the disease.

3. That state and local health authorities, the military services, and institutions, in addition to collecting their usual records, undertake such statistical and field studies as circumstances will permit, and that they be especially on the alert to take advantage of any opportunities which may be presented for unusually instructive epidemiological observations.

4. We would also call attention to the need for extensive and careful clinical studies, particularly such as will give accurate descriptions of unselected cases, including the milder types of doubtful diagnosis.

In addition to the general subject, two specific questions have been referred to this committee.

First: Is it desirable that influenza be included in the list of notifiable diseases? We believe that it should be so included, at least to the extent of simple numerical statements.

Second: Should an official clinical definition of influenza be adopted by this Conference for the guidance of physicians in differentiating influenza from other respiratory disorders to the end that morbidity reports should be more uniformly comparable? We believe that this is not advisable.

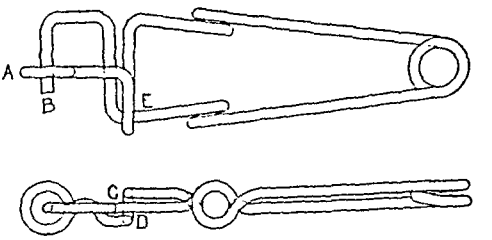
Immunization in Scarlet Fever—A group of 9,780 school children of known skin test were selected for observation for a period of 3 years. During this time 182 contracted scarlet fever. In accordance with the result of the skin test the children have been divided into five groups. There were 3,424 who gave a negative skin test, of whom 16 developed scarlet fever, giving an incidence rate of 4.7 per 1,000. There were 2,289 in the group with (±) skin test (diameter of reddened area 0.5–1.0 cm.), and of these, 21 contracted scarlet fever, giving an incidence rate of 9.2 per 1,000. In the group with (+) skin test (1.0–1.5 cm.) there were 2,099 children, of whom 48 contracted scarlet fever, giving an incidence rate of 22.9 per 1,000. There were 1,528 children with a (++) skin test (1.5–2.5 cm.). In this group 73 contracted scarlet fever, giving an incidence rate of 47.5 per 1,000. There were 440 in the group with a (+++) skin test (2.5 cm. and larger). Among this group 24 cases of scarlet fever developed, giving an incidence rate of 54.5 per 1,000. These figures show that the more intensively positive the test, the higher is the incidence rate of scarlet fever. If contracted by negative and slightly positive reactors, the disease is generally mild, especially so far as the rash is concerned.

Among 1,825 children completely immunized against scarlet fever with a dosage of from 30,000 to 50,000 skin test doses, 1 case of scarlet fever developed, giving an incidence rate of 0.6. Among 636 incompletely immunized, 11 cases developed, with an incidence rate of 17.3. Among 832 known immunized children 40 cases developed, with an incidence rate of 48.1.—George Moriwaki, Correlation between the Skin Test and Active Immunization in Scarlet Fever, *J. Prev. Med.*, 3: 13 (Jan.), 1929.

LABORATORY

C. C. YOUNG

A NEW MICRO SLIDE HOLDER



PHILIP L. VARNEY

Washington University, St. Louis, Mo.

OF THE numerous slide holders obtainable for use in staining procedures, none are constructed to grip the slide in a manner to prevent effectually the overflow and spilling of the stain, due to capillarity, when the slide is flooded, as in acid-fast staining. The slide holder described here was designed to prevent such repeatedly experienced accidents. The slide may be held very rigidly by the use of such a device.

Figures I and II illustrate the construction of the slide holder, which should be made of phosphor-bronze wire 2.5 mm. in diameter. The most convenient length for ordinary staining purposes is 15 cm., and the width at the widest point 3.5 cm. It is so constructed that by compressing the handle of the holder the tip (B) is forced upward, leaving a gap between it and the platform or ring (A), in which the slide is placed. When the pressure on the handle is removed, the slide is gripped and held firmly.

Side movement of the tip (B) is prevented by means of the guards (C) and (D), between which the wire (E) slides. These guard wires must be of such a length that with the micro slide in place (E) will still be between the guards, thus effectually preventing any trace of sideward movement and the consequent dropping of the slide.

FIGURES I AND II

The micro slide may be held with any desired tension, by removing (E) from between its guard wires and bending the spring backward or forward in the desired direction, thus increasing or decreasing the tension. Any size slide may be held without danger of its turning or of the stain overflowing even when the slide is flooded to the extreme edge.

CASES OF DYSENTERY IN NEW YORK STATE ATTRIBUTED TO B. DYSENTERIAE SONNE

RUTH GILBERT, M. D., AND M. B. COLEMAN

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

CASES of dysentery attributed to the lactose fermenting bacillus described by Sonne[1] have seldom been reported in this country, although dysentery due to infection with this organism has been recognized in Australia,

Europe, England, and Scotland, where a milk-borne epidemic occurred in 1926.[2] The symptoms described have usually been less severe than those following a *B. dysenteriae* Flexner infection, but recently two fatal cases[3, 4] have been reported in England.

B. dysenteriae Sonne corresponds to the Flexner and Mt. Desert types in morphology and in the reaction produced in triple-sugar agar. The biochemical characteristics, however, show certain marked differences. Lactose is fermented slowly; the formation of appreciable amounts of acid in medium containing this carbohydrate may be delayed 10 days or longer in the case of some freshly isolated strains. Mannitol is fermented; maltose and saccharose may or may not be, and when they are, the reaction is slow. Acid is produced slowly in milk. Indol is not formed. In polyvalent dysentery immune serum prepared with the nonlactose fermenting strains, cultures of the Sonne dysentery bacillus are usually agglutinated only in low dilutions. Even in homologous serums they may be inagglutinable when freshly isolated, but, after being transferred daily for from 1 to 2 weeks, a specific reaction is obtained. Agglutination of the culture in patients' serums is believed by Sonne and others to be of definite significance.

Within a few months, 12 strains of this organism, 8 of which were isolated either in the branch laboratory or in county laboratories, have been identified. All were obtained from fecal specimens from patients reported to have more or less severe symptoms of dysentery, bloody stools being noted in 4 cases. No deaths have as yet been reported. Unusually dilute suspensions of the cultures absorb the agglutinative properties of a serum prepared with a strain of *B. dysenteriae* Sonne obtained from the American Type-Culture Collection.

In only 1 instance were any other organisms of diagnostic significance found. *B. typhosus* was isolated from a specimen of feces received from one patient 2 days before the specimen was received in which *B. dysenteriae* Sonne was found. The clinical manifestations were typical of typhoid fever. It seems probable either that this was a double infection or that the patient was a carrier of the dysentery bacillus, since other patients in the same hospital were suffering from dysentery and *B. dysenteriae* Sonne was isolated from their stools.

Four of the 12 cases described occurred in two state hospitals, and 5 in a city during an epidemic of enteric disease attributed to a polluted water supply. The remaining 3 were in widely separated counties. This distribution indicates that infection with *B. dysenteriae* Sonne may be more prevalent than has previously been supposed.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Principal Causes of Death in 1927—The Department of Commerce announced that 1,236,949 deaths occurred in 1927 within the death registration area of continental United States, representing a death rate of 11.4 per 1,000 population, the lowest since 1900. The principal decreases in death rates were for pneumonia (all forms) from 102.5 per 100,000 population in 1926 to 80.5 in 1927, for influenza from 40.7 to 22.6, tuberculosis (all forms) from 87.1 to 80.8, diarrhea and enteritis (under 2 years) from 27.0 to 21.6, nephritis from 98.3 to 92.5, measles from 8.2 to 4.1, and diseases of the heart from 199.1 to 195.7. An increase is shown in the death rates from automobile accidents from 17.9 per 100,000 population in 1926 to 19.5 in 1927. Other causes of death that showed increased death rates for 1927 were diphtheria, malaria, cancer and other malignant tumors, and suicides.—U. S. Dept. of Commerce, *Press Release,* Dec. 21, 1928.

Preliminary Report on Marriage and Divorce for the United States, 1927—There were 1,200,694 marriages performed in the United States during the year 1927 as compared with 1,202,574 in 1926. These figures represent a decrease of 1,880 marriages, or about 0.2 per cent. The number of marriages per 1,000 population was 10.12 in 1927 as against 10.27 in 1926. During 1927 there were 192,037 divorces granted, as compared with 180,853 in 1926. This is an increase of 11,184, or 6.2 per cent. There were 4,252 marriages annulled in 1927, as compared with 3,825 in 1926. While the net decrease in the number of marriages performed in the country as a whole was 0.2 per cent, the relative change in the different states ranged from a decrease of 25.4 per cent in Florida to an increase of 95.3 per cent in Nevada. The number of marriages per 1,000 population in 1927 ranged from 4.7 in Delaware and 5.8 in Wisconsin to 31.0 in Nevada and 16.6 in Mississippi. These figures may be compared with those of 1926, being 4.6 per 1,000 population for Delaware, 5.8 for Wisconsin, 15.9 for Nevada and 16.0 for Mississippi. The number of divorces showed a range of increase from 1.1 per cent in Oregon to 52.1 per cent in the District of Columbia and 91.3 per cent in Nevada. The decreases in divorces ranged from 35.3 per cent in Vermont to 1.9 in Missouri. The figures for Vermont and Nevada are due to changes in the divorce laws, effective in 1927. The number of divorces per 1,000 population was 25.2 for Nevada in 1927 as compared with 13.2 in 1926. In the District of Columbia there were 0.27 divorces per 1,000 population as compared with 0.18 in 1926.—U. S. Department of Commerce, *Press Summary,* Dec. 17, 1928.

Mortality Figures of the Willard Parker Hospital—In 1922, 4,409 cases were treated at Willard Parker Hospital. These resulted in 737 deaths, a mortality of 16.7 per cent. In 1924 the general mortality for 3,320 cases was 10.9 per cent; and in 1927 for 3,323 cases, it was 7.3 per cent. Between 1922 and 1927 the general mortality was reduced 56.3 per cent. Between the years 1922 and 1927, the diphtheria mortality at Willard Parker Hospital

fell from 18.1 to 9.0 per cent, a reduction of 50.3 per cent. Improvement in the treatment of laryngeal diphtheria "croups" by suction was responsible in a large measure for the reduction of the diphtheria death rate. In 1922, 14.2 per cent of the cases treated were intubated, and 53.8 per cent of these died. In 1927, 4.5 per cent of the cases treated in the hospital were intubated, and 16.7 per cent died. There were 1,158 cases of measles in 1922, and 22.5 per cent of these died. In 1925, a non-epidemic year, 6.2 per cent of 660 cases died, and in 1927, 9.1 per cent of 220 cases died. During 1922 there were 895 cases of scarlet fever treated which had a mortality of 8.4 per cent, as against 936 cases treated in 1927 which had a mortality of 2.4 per cent. The reduction of the scarlet fever mortality was largely influenced by the use of serum in the treatment of severe cases. —Shirley W. Wynne, *New York State J. Med.*, 29: 12–13 (Jan. 1), 1929.

The Health of Gibraltar—During 1927 the corrected death rate of Gibraltar was 20.3 per 1,000 population, while the crude rate was 17.3. The birth rate was 22.5 per 1,000, and the infant mortality rate was 99 deaths per 1,000 live births. There were 16 deaths from cancer, 1 from diphtheria, 9 from influenza, 27 from pneumonia and 30 from tuberculosis. The death rate from pulmonary tuberculosis was high, being 1.3 per 1,000 population.—*Med. Off.*, 40: 223 (Nov. 24), 1928.

VITAL STATISTICS FOR 1928

New York, N. Y.—The Health Department of New York reported that there were 77,677 deaths from all causes during 1928. This gives a death rate of 12.9 per 1,000 population, as compared with 12.2, the average rate for the previous 5 years. The total number of births during 1928 was 126,332, a decrease of 2,556 from 1927, and 3,758 from 1926. Deaths among infants totalled 8,279, giving a rate of 66 infant deaths per 1,000 births. During the year there were 641 deaths from diphtheria, 17,079 from heart disease, 4,611 from pulmonary tuberculosis, 9,951 from pneumonia, 891 from influenza, 7,677 from cancer, and 514 deaths from meningitis.—*New York Times*, Jan. 2, 1929; *New York Sun*, Jan. 2, 1929.

Newark, N. J.—Newark's birth rate for 1928 is the lowest on record in the city. There were 9,886 births during the year, giving the low rate of 20.9 births per 1,000 population. The estimated number of deaths under 1 year of age is 620 for the year, giving an infant mortality rate of 63 per 1,000 births. The estimated number of deaths for the year was 5,670, giving a general mortality rate of 11.5 per 1,000 population. This is a slight rise over 1927 when the rate was 10.9 per 1,000. Typhoid fever showed the greatest reduction of deaths, with the low death rate of 1.05 per 100,000 population. The nearest approach to this record was in 1925 when the rate was 1.1 per 100,000. Scarlet fever had a death rate of 1.5 as compared with 2.6 for 1927; whooping cough had a rate of 4.4 for 1928, and 6.6 in 1927; heart disease had a rate of 208.9 in 1928, and 217.9 for 1927. The greatest increase was shown by measles, with a mortality rate of 10.1 per 100,000 for the year as compared with a rate of 0.7 in 1927. Another marked increase was shown by pneumonia with a mortality rate of 129.7 as compared with 103.8 for 1927.—*Newark News*, Dec. 29, 1928.

Hoboken, N. J.—According to the registrar of vital statistics there were 1,159 births in Hoboken for 1928, as compared with 1,225 for 1927. The birth rate in 1928 was 16.6 per 1,000 population as compared with 17.9 for 1927. There were 645 deaths from all causes in 1928, giving a death rate of 9.2 per 1,000 population, as compared

with 651 deaths with a death rate of 9.3 in 1927. In both 1928 and 1927 the greatest number of deaths occurred between the ages of 50 and 60 years. There were 116 deaths from pneumonia in 1928, as against 101 in 1927. Thirty-five deaths were caused by tuberculosis in 1928, as compared with 37 in 1927. There were 35 deaths from cancer in 1928 as against 45 for the preceding year.—*Jersey Observer,* Jersey City, N. J., Jan. 16, 1929.

Milwaukee, Wis.—The 1928 death rate for Milwaukee was 10.7 per 1,000 population. The infant mortality rate was 68 deaths per 1,000 live births. There were 1,710 cases and 10 deaths from scarlet fever, as compared with 1,362 cases and 7 deaths in 1927. Whooping cough had 1,943 cases and 24 deaths compared with 1,114 cases and 16 deaths the previous year. Influenza showed a marked increase, with 77 deaths compared with 21 in 1927, and pneumonia showed 532 deaths, compared with 491 in 1927. Typhoid fever with 16 cases and 4 deaths showed the lowest typhoid record in the history of the city. Diphtheria showed an improvement, with 349 cases and 30 deaths, compared with 694 cases and 49 deaths in 1927. Tuberculosis showed a decrease for 1928 with 263 deaths compared with 292 in 1927.—*Milwaukee Journal,* Dec. 31, 1928.

San Francisco, Calif.—Up to December 26 there were 7,928 births in San Francisco for the year 1928. During 1927 there were 8,344 births. The number of deaths from all causes has increased from 7,826 in 1927 to 8,151 up to December 26, 1928.—*San Francisco Bulletin,* Dec. 31, 1928.

Omaha, Neb.—There were 2,748 deaths from all causes in Omaha during 1928, giving a death rate of 12.3 per 1,000 population. The total deaths from all causes in 1927 were 2,687. There was a rate of 20.0 births per 1,000 population, and a rate of 48 infant deaths per 1,000 live births. Pneumonia with a rate of 162.9 deaths per 100,000 population was the leading cause of mortality. Tuberculosis followed with a rate of 44.0; diphtheria with 5.8; typhoid fever 2.7; whooping cough 0.9; erysipelas 0.9; and scarlet fever with a death rate of 0.4 per 100,000 population. There were 312 cases of diphtheria, 37 of measles, 247 of scarlet fever, 101 of smallpox, 59 of mumps, 50 of whooping cough, 21 of typhoid fever, and 3 cases of erysipelas. —*World Herald,* Jan. 1, 1929.

Butte, Mont.—Deaths exceeded births in Butte during 1928. There were 1,001 deaths and 880 births for the year. During 1927 there were 879 deaths and 912 births.—*Montana Standard,* Jan. 10, 1929.

Regina, Sask.—The total number of deaths in the city of Regina for 1928 was 527, as against 395 in 1927. There were 1,360 births, as against 1,215 for the previous year. There were no serious epidemics in the city during 1928. —*Regina Post,* Jan. 8, 1929.

Toronto, Ont.—There were 6,883 deaths from all causes in Toronto during 1928, as compared with 6,285 for 1927. There were 607 deaths from pneumonia for 1928, as compared with 430 for 1927. Influenza combined with pneumonia resulted in 246 deaths for 1928, as compared with 109 for 1927.—*Daily Times,* Moncton, N. B., Jan. 3, 1929.

Quebec, Que.—Mortality figures in the city of Quebec for 1926, 1927 and 11 months of 1928 showed evidence of progress especially in the combating of contagious diseases. The death rates per 100,000 population from all causes for 1926, 1927 and 1928 respectively were 195.9, 120.0 and 64.1 for Beauce County; 160.3, 163.9 and 111.0 for Lake St. John County; 125.2, 86.7 and 55.1 for St. Hyacinthe County; and 89.9, 91.8 and 62.8 for Joliette County. —*Montreal Star,* Jan. 15, 1929.

Diphtheria Deaths in Massachusetts, 1927—During 1927 there were 4,750 diphtheria cases and 268 deaths reported in Massachusetts. The case fatality rate of 5.6 per cent is the lowest on record in the state. The mortality rate of 6.3 per 100,000 population is the second lowest on record, only being surpassed by the rate of 5.9 in 1926. A study of 117 diphtheria deaths occurring during 1927 was made, based upon a personal investigation by the State District Health Officers. Among the 117 deaths, 47.8 per cent were under 5 years of age, and 34.0 per cent were between the ages of 5 and 10 years. The largest percentage of deaths, 13.7, occurred among those aged 2 years. A physician was called at some time during the course of the illness in each of the 117 cases investigated. In a total of 94 cases, the economic status of 22 was good. Among 18.2 per cent of those of good economic condition the physician was called on the first day of illness, among 27.2 per cent the physician was called on the second day, and among 22.7 per cent, on the third day. The economic status of 42 of the 94 cases was fair. Among 7.1 per cent of these a physician was called on the first day of illness, among 11.9 on the second day, and among 33.4 on the third day of illness. Thirty of the cases had a poor economic status. Thirteen and three-tenths per cent of this class called a physician on the first day of illness, 10.0 per cent on the second day, 6.7 per cent on the third day, and 20.0 per cent on the fourth day of illness. Fifty-seven per cent of 112 patients were hospitalized. In 6 of 106 cases, the physician was said to have failed to make a primary clinical diagnosis of diphtheria. Antitoxin was administered in 114 of the 117 cases studied. The largest individual dose administered was 100,000 units; the smallest, 500 units. The largest total amount given any one case was 200,000 units; the smallest, 2,000 units. In 73.0 per cent of 96 cases, the physician administered antitoxin on the day of his first visit. In 11.5 per cent of the cases, antitoxin was administered 1 day after the first visit of the physician. The Schick test had never been performed on 102 of the 117 cases studied. Information is lacking for the remaining 15 cases.—Edward A. Lane, *New England J. Med.*, 199: 939–944 (Nov. 8), 1928.

Health in Iceland—During 1926 Iceland had a death rate of 11.1 per 1,000 population, and a birth rate of 26.1. The infant mortality rate was 49 per 1,000 live births. Three outbreaks of typhoid fever, which were traced to milk, caused 175 cases and 13 deaths. The outbreaks were overcome by isolation and preventive vaccinations. Seventy-one cases of diphtheria, mostly of a mild type, caused 2 deaths. The death rate from pneumonia was about 1 per 1,000 population, and the rate from bronchitis was 0.09 per 1,000. There were 3,115 cases of influenza, as against 941 in 1925. The death rate from tuberculosis was very high, about 2 per 1,000 population, and shows no tendency to decline. Tuberculosis of the lungs is more frequent in women than in men. About 20 per cent of the tuberculosis deaths were due to the meningeal form of the disease. There were 4 deaths from puerperal causes, a rate of 1.5 per 1,000 births. Thirty-two cases of syphilis were reported, including 14 foreigners, and 236 cases of gonorrhea, including 41 foreigners. The number of lepers showed a decrease. In 1921 there were 63, and in 1926 there were 49.

Vaccination has been legally enforced since 1910. In 1926, 3,060 children were vaccinated for the first time, and 2,215, aged 12 to 13, were revaccinated. —*Lancet*, 215: 828 (Oct. 20), 1928.

Heart Disease in Children—This study is based on the statistical analysis of case histories of 500 children, from infancy to 22 years of age, observed in a clinic under the same medical supervision during the 10-year period 1916–1927. Congenital heart defects occurred in 11.2 per cent of the total cases. Five and four-tenths per cent of the patients had definite organic diseases of unknown etiology. Twenty-five children, classified as harboring possible heart disease, had negative histories, slight heart enlargement and persistent systolic murmur. Of these children, 20 retained the same physical signs over the period of observation. Rheumatic infection occurred in 395, or 79 per cent of the 500 cases.

The average age of onset in 413 cases of rheumatic infection was 7.3 years. Recurrence of infection occurred in 85 per cent of those with initial infection at ages 3 to 5 and in 63 per cent of those infected after age 10. In 67.8 per cent of the rheumatic cases the duration of the disease had been from 1 to 5 years, in 21.8 per cent from 6 to 9 years, and in 10.2 per cent from 10 to 16 years.

A history of measles was present in 53.7 per cent of the cases, occurring between the ages of 3 and 5 years, in 36.9 per cent. Scarlet fever occurred in 10.2 per cent of the children. In 38.2 per cent of the cases it occurred between the ages 6 and 9 years. Polyarthritis occurred from 1 to 6 times in 65.8 per cent of 272 rheumatic children. Growing and joint pains occurred in 67 per cent of the 413 rheumatic children and were the first manifestations of infection in 26.6 per cent of the children. In 23 per cent of the cases the pains preceded polyarthritis, and in 10.9 per cent were followed by acute carditis. Forty-four and five-tenths per cent of the children gave a history of acute rheumatic carditis, or presented an attack while under observation. Heart involvement was exhibited in 79.5 per cent of the cases. On final examination 49.8 per cent of the rheumatic cases showed slight heart enlargement, 30.6 per cent moderate, and 17.6 per cent showed marked enlargement. Twelve per cent of the rheumatic children died, 22 per cent of the deaths occurring within 1 year of the onset of the infection. The most common age at death was between 11 and 14 years.—M. Wilson, C. Lingg and G. Croxford, Statistical Studies Bearing on Problems in the Classification of Heart Disease, *Am. Heart J.*, 4: 164–196 (Dec.), 1928.

Vital Statistics of Vienna, 1927—The population of Vienna for 1927 was 1,866,147, or 29 per cent of that for the whole republic. The total number of births in Vienna was 21,337 as compared with 24,064 in 1926. There were 26,379 deaths from all causes for 1927, and 25,378 for 1926. Infant deaths numbered 1,749, as contrasted with 1,889 in 1926. There were for the year 1927, 3,818 deaths from tuberculosis, and 3,882 for 1926; 2,308 deaths from pneumonia, and 2,386 for 1926; 198 deaths from diphtheria, and 99 for 1926; 76 deaths from scarlet fever, and 41 for 1926; 133 deaths from measles, and 9 for 1926; 33 deaths from typhoid fever, and 41 for 1926; 85 deaths from puerperal sepsis, and 37 for 1926.—Marriages, Births and Deaths in Vienna in 1927, *J. A. M. A.*, 92: 247 (Jan. 19), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Progress Report of the Committee on Milk Supply *—Last year the Committee on Milk Supply submitted to the section a tentative draft of standard pasteurization plant requirements based upon the U. S. Public Health Service Standard Milk Control Ordinance and Code.† These requirements were printed as a supplement to the May, 1928, issue of the *American Journal of Public Health and The Nation's Health*, with the statement that the committee would welcome constructive criticism on the report for its guidance.

The committee has carefully reviewed the suggestions offered, and submits certain amendments for its 1928 report. Some of the more important of these amendments are:

1. Means for preventing contaminated condensation on the headers of milk coolers from entering the milk
2. The elimination of cloth strainers after pasteurization
3. A requirement relating to the finish of walls and ceilings
4. More rigid fly exclusion requirements
5. More specific requirements for milk pump materials
6. An item admitting consideration by state health departments of new methods of pasteurization demonstrated to be of at least equal efficiency
7. A requirement forbidding transportation of milk between pasteurization and bottling
8. The inclusion of new and detailed requirements for thermometers used in pasteurization process control, as formulated by a conference of the U. S. Public Health Service, the U. S. Bureau of Standards, the U. S. Department of Agriculture, and representatives of the principal American Instrument Manufacturers (held in April, 1928)
9. A requirement that the temperature shown by the indicating thermometers and the recording thermometer charts continuously throughout the holding period must be at least the temperature which the definition of pasteurization requires the thermometers to show

The committee wishes to repeat its invitation to the members of the section and of the Association to submit suggestions during the coming year.

Your committee further wishes to advise that the above report has been considered, and agreed upon jointly with the Committee on Milk Sanitation of the Conference of State Sanitary Engineers.

Control of Malaria and Mosquito Breeding at the Marine Barracks, Quantico, Va., during the Year 1927 —This is a summary of the work done in the control of malaria and mosquito breeding at the Marine Barracks, Quantico, Va., during the year 1927, with a brief description of the personnel employed, their duties, material used with cost, and methods of control employed.

As a result of his studies the author concludes that with the use of airplanes: (1) 33 per cent Paris green in an inert dust is the most satisfactory strength under all wind conditions; (2) 1 pound of Paris green per acre is the proper unit; (3) material cost is approximately 70 cents per acre per season.

To show how effective has been the control the author cites that in 1922 the malaria admission rate was 28.26 per 100 and 0 in 1927.—W. M. Garton, *U. S. Nav. M. Bull.*, 26, 3: 747–754 (July), 1928. Abstr. O. C. Hopkins.

---

* Presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

† This ordinance and code will be revised and printed by the U. S. Public Health Service in the near future.

Sanitary Engineering Aspects of Shellfish Pollution—This article gives a historical sketch of the relationship between oysters and public health. The author further discusses successively the biology of shellfish, the problem of pollution, both by domestic and industrial wastes, and specific Chesapeake Bay problems. Domestic sewage is dangerous from the standpoint of infecting the oyster, and if present in sufficient quantities destroys the oyster by virtual depletion of oxygen. Certain industrial wastes, such as cannery wastes, destroy oysters in the same way, while other industrial wastes, such as oil and tannery wastes, destroy oysters by virtue of toxicity.

Oysters may be contaminated and infected by growing in polluted waters and by improper handling. The floating of oysters for "fattening" is frowned upon by most authorities.

This article also contains a report of a survey by the Maryland Department of Health in the Chesapeake Bay problem, together with the laboratory findings.—Carl Speer, Jr., *Bulletin*, Maryland State Dept. of Health, 1, 3: 16–57 (Apr.), 1928. Abstr. A. H. Wieters.

An Outbreak of Infectious Diarrhea on Board the U. S. S. Melville, Attributed to Contamination from Gatun Lake, Canal Zone—At the time the U. S. S. Melville was in transit through the Panama Canal from Balboa, Canal Zone, to Colon, Panama, in March, 1927, about 6,000 gallons of water from Gatun Lake were taken on board for use in the boilers and stored in the ship's tanks after distillation. The cloudy appearance and unpleasant taste of the water attracted attention, so that samples of the water were collected and cultures made which indicated a heavy pollution of the water with *B. coli*. At the same time a number of the crew developed symptoms of mild enteritis.

Following the isolation of *B. coli* from the fresh water supply of the ship and the appearance of acute cases of enteritis among the crew, the water was pumped overboard and all tanks cleaned. They were then filled with freshly distilled water and disinfected by the addition of a solution of chlorinated lime. After this procedure no other cases of enteritis developed at the time. No water was taken on board during the return trip, so that water in tank No. A2, to which a later outbreak of acute enteritis was attributed, must have been overlooked when the other tanks were emptied, cleaned and disinfected.

On June 30, a junior dentist on board became ill with symptoms of severe gastroenteritis. On July 12 and 13, a number of patients were admitted to the sick list.

Cultures were made from the fresh fruits, vegetables, the scuttle butt and each individual tank. Water from the scuttle butt was found to be heavily contaminated with *B. coli*, and water from tank No. A2 gave a growth of a Gram-negative, motile bacillus later identified as *Bacillus fecalis alcaligines*. As a result of the investigation to determine how the contamination of the water in tank No. A2 had taken place it is believed either that water from Gatun Lake found its way into this tank through an open valve, or that infected water was delivered by the ship's evaporators to the tanks while in Gatun Lake.—Dallas G. Sutton, *U. S. Nav. M. Bull.*, 26, 3: 727–732 (July), 1928. Abstr. O. C. Hopkins.

Phenol Pollution of Public Water Supplies in the Middle West—This article discusses in some detail the development of control measures in connection with the pollution of public water supplies by phenol wastes from by-product coke plants. Mention is first made of the pollution of the water

supply of McKeesport, Pa., where the city secured a permanent injunction in 1918 against the Clairton By-Product Coke Plant of the Carnegie Steel Company to prohibit the discharge of their wastes into the stream. The company promptly developed a method of utilization of the waste in quenching the coke. Approximately $1,000,000 was spent by the company to eliminate this nuisance. Mention is also made of the interstate conferences arranged by the Surgeon General of the U. S. Public Health Service on May 18, 1923, January 24, 1924, and at Pittsburgh, Pa., on April 14, 1925. On November 17, 1924, an interstate stream conservation agreement was entered into by the states of Ohio, Pennsylvania, and West Virginia. Since this time the states of Kentucky, New York, Maryland, Illinois, Indiana, and Tennessee have joined the agreement, which provides for a coöperative program to control the pollution, and to notify the various plants of accidents or "spills."

Sources of phenol from by-product coke plants are given as follows:

Waste	Per cent phenol in plant waste	Approximate lbs. phenol per ton of coal carbonized
Ammonia still ...	70 to 80	0.3 to 0.5
Final cooling water	20 to 25	0.02 to 0.08
Benzol plant wastes	2 to 5	certain taste producing light oils
Gas condensate waste	Variable	certain taste producing light oils

Three methods of phenol elimination are mentioned: coke quenching, extraction of the phenol, and biological absorption. Objections to the quenching process include discoloration of the coke by lime deposited from the ammonia still wastes, disagreeable phenol odors, and deterioration of metallic equipment in the vicinity of the quenching tower by chloride from the lime waste, estimated at $200,000 annually at one plant with 10 quenching towers.

The extraction process was first developed at the National Tube Company, Lorain, O., in 1924, with a recovery of 76 per cent of the phenol. Later, plants were installed at the Iroquois Gas Corporation, Buffalo, N. Y., in 1925; at the Hudson Valley Coke Corporation, Troy, N. Y., in 1926; and at the Domestic Coke Corporation, Fairmont, W. Va., in 1927. These plants have developed an efficiency of 97 per cent. The cost at Fairmont was $25,000 for 1,000 tons coal daily capacity, and at Troy, $60,000 for 3,750 tons coal daily capacity. It is stated that the operation is self-sustaining. After tests at Rochester, N. Y., gas plant wastes were received in the public sewers with no deleterious effects to the Imhoff tanks. Rather detailed information is then given regarding the recovery installations at other places.

The conclusion contains an application of the data to the Sanitary District of Chicago, with certain recommendations.—Herman N. Bundesen, *Water Works*, 67, 6: 240–246 (June), 1928. Abstr. C. M. Baker.

Effect of Certain Illinois Waters on Lead—The preparation of this article was brought about by an investigation of a case of sickness in Champaign, Ill., which was diagnosed as lead poisoning. An analysis of the water which the patient had been drinking showed 0.08 p.p.m. of lead present.

The opinions of various authorities on the allowable limits of lead in water are cited. There are some data on the important factors causing the solution of lead as well as a short résumé on the analytical determination of lead. There are also tables showing compiled data on lead in water and a discussion of the effect of Illinois waters on lead. The

article is concluded with some authoritative data on prevention of lead corrosion. A bibliography is given on the subject.—O. W. Rees and A. L. Elder, *J. Am. Water Works A.*, 19, 6: 714–724 (June), 1928. Abstr. A. L. Dopmeyer.

Anopheles Density Index in Malaria Research and Control Work—The author calls attention to the value in any malaria investigation of the anopheles density index and gives directions as to the proper method of obtaining such index. In the vicinity of the field station of the Bureau of Entomology at Mound, La., the numbers of anopheles found under the houses of tenants on cotton plantations afford a good basis for determining density indices. The author illustrates by a series of charts and tables which exhibit the anopheline density indices of several plantations near Mound for different months of the year and for various years. A remarkable fall in the density of the region is recorded for the three years following 1923, a diminution due to droughts. The highest monthly index occurs in July. The flood of 1926 destroyed much of the aquatic vegetation in the lakes near Mound, and it may be some years before the normal production of anopheles is reëstablished there.—W. V. King, *South. M. J.*, 21, 9: 763–767 (Sept.), 1928.

Dissolved Iron and Manganese in Stored Water at Kernersville—This valuable contribution to the limited literature of manganese and iron removal reviews unusual problems developed at Kernersville, N. C., when a new filtration plant designed to treat a typical turbid water of a flowing stream was placed in operation to treat the same water after storage in a shallow reservoir containing large quantities of organic matter. Storage of this water led to a marked change in its quality, leading to the solution of manganese and iron from mineral deposits at the site and to a large increase in the color of the water. Experiments conducted at the plant indicate that aeration of the water failed to precipitate the iron and manganese, probably due to the large organic content.

Pre-chlorination of the water, however, led to the precipitation of the iron and manganese, but the organic color remained unchanged. Addition of lime to the raw water produced excellent flocculation of the iron and manganese, but no change in the organic color. Subsequent coagulation with alum, however, resulted in a reduction of the color. Experiments were duplicated on a plant scale by the addition of lime to the raw water entering the mixing basin. The dose of lime was determined by the maintenance of a faintly caustic reaction to phenolphthalein. The formation of the iron hydroxide was extremely rapid, allowing the alum solution to be added about half way down the mixing chamber. The alum dose was adjusted to maintain the optimum pH for color coagulation. The sedimentation of the floc, however, was slow, so that the settled water was more turbid than desirable, thus requiring frequent washing of the filters and the use of large volumes of wash water.

The above situation indicates the great desirability of thoroughly studying the quality of a raw water to be treated before the final plans for water purification plants are completed, in order that the plant may be provided with the necessary auxiliary equipment and for special treatment when such is necessary.—W. H. Weir, *J. N. C. Section Am. Water Works A.*, 5, 1: 119–126, 1927. Abstr. C. R. Cox.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

The Biochemical Reaction of Lead in the Body—The article reviews the theories and findings concerning the distribution and form of lead in the body, and of equilibrium between its soluble, or toxic diphosphate form, and its insoluble, or non-toxic triphosphate form. Since lead is in the blood, it comes in contact with all of the body tissues and this accounts for its multiple symptoms, which are usually grouped by the systems involved; the blood, the gastrointestinal tract, the nervous system (both central and peripheral), the skeletal system (both muscles and joints), the cardio-vascular system, the urinary system, the reproductive system (the germ cells).—May R. Mayers, *Indust. Hyg. Bull.*, New York State Dept. of Labor, 5, 7: 26–28 (Jan.), 1929.

Standards for Workmen's Compensation Laws—The proposed standards concern: I. The scale of compensation, including the matter of medical attendance; waiting period; compensation for total disability and for partial disability and for death, the latter including funeral expenses; compensation for the widow or widower or children or other relatives, or alien non-resident dependents, including the maximum and minimum compensation for death; and the commutation of periodical compensation payments. II. The employments to be included. III. The injuries to be included, taking into consideration occupational diseases. (Occupational diseases are now compensated in California, Connecticut, Hawaii, Massachusetts, North Dakota, the Philippines, Wisconsin, under the three federal laws, and to a limited extent in Illinois, Minnesota, New Jersey, New York, Ohio and Porto Rico.) IV. Other remedies than those provided for by the Compensation Act. V. Security for the payment of compensation awards. VI. Organization of the accident board. VII. Procedure for settlement of compensation claims. VIII. Reports of accidents. IX. Rehabilitation.—Committee on Workmen's Compensation, American Association for Labor Legislation, *Special Bulletin*, Revised to Jan. 1, 1929 (131 East 23d Street, New York, N. Y.).

The Problem of Industrial Health—The factory worker "goes stale" because of the monotony of his work, and the executive, because of (mental) strain. Physical examinations show about the same disabilities in both. Six chief causes of death—diseases of the heart and circulation, tuberculosis, cancer, apoplexy, kidney disease and diabetes—constitute nearly one-half of the 1,219,019 annual deaths in the 40 to 50 million "gainfully employed" in the country. These chronic diseases represent "silent sickness," because during the greater part of their duration no obvious disability is shown. Dr. Charles H. Mayo states that 86 per cent of all deaths are due to infections, and the same chronic infections exist in the worker as in other members of society. No adjustment of working hours or operations will meet "silent sickness" and its fundamental control lies in periodic health examinations, which the Metropolitan and Guardian Life Insurance Companies have shown will decrease mortality from 18 to 23 per cent (charts accompany).

Not only the man on the sick list, but the man who is one-half, one-quarter, or one-tenth sick must be considered. Disabilities are liabilities which have a cumulative effect. Any program which permits the man over 40 to be considered a physical and economic liability is unsound, while a thorough-going program of prevention, joined up to a mutual benefit association, would save enough lives in industry to offset the need for foreign labor. The worker's best investment of his own time, interest and some of his money is in his health. A reasonable coöperative plan is all that is needed.—Eugene L. Fisk, *Law and Labor,* X, 9: 196–200 (Sept.), 1928.

The Health of the Wage-earner—Industry must solve the cost of sickness in workers, or state legislatures will soon do so to the increased cost of goods. The Life Extension Institute states that the cost of preventable sickness and death among the gainfully employed in this country amounts to $1,800,000,000 annually, which represents half of the total disability. The answer is periodic health examinations. The Metropolitan Life Insurance Company states that there has been a reduction of 18 per cent in mortality, and the Guardian Life Insurance Company places it at 23 per cent, as the result of such examinations, while at some ages the reduction has been 50 per cent. Spending $100 a year on a machine to keep it in good condition, to be operated by a man who is only 50 per cent fit, is poor economy. The expense of health supervision should amount to 1½ per cent of the pay roll. This cost should be divided 50–50 with employes and the fund handled by a mutual benefit association which invests in a group life insurance policy. It should also provide two-thirds pay for 26 weeks and a competent physical examination annually. If properly run, such a plan will lay up from 20 to 40 per cent of its income, which can be spent for numerous accessory needs. The writer cites examples of benefits to employes in his own construction company "because we have a plan that is working along the right lines."—Harold A. Ley, *Law and Labor,* X, 9: 189–194 (Sept.), 1928.

Lead Poisoning from Lead Piped Water Supplies—Most lead poisoning is attributed to certain occupations. The Industrial Clinic of the Massachusetts General Hospital found almost 11 per cent of lead poisoning, however, to be of non-industrial origin. A chemical study of 102 lead conducted water supplies in Massachusetts towns showed that all contained lead. The lead content was most strikingly related to the carbon dioxide content. Of 253 exposed persons, 63, or 24.9 per cent, were poisoned. The incidence was less in young children and greater in adults. Women showed a lower incidence of poisoning than men.—Wade Wright, *J. Indust. Hyg.,* 10, 7: 234–235 (Sept.), 1928.

Tuberculosis as an Industrial Accident—Closely analyzing 76 cases (Mass.) in which tuberculosis of the lungs was the "personal injury" involved, and for which compensation was demanded, has resulted in some interesting findings. Of the cases, 27 were granite workers with an average of 30 years' exposure. In the case of 12 others there could be no doubt that the tuberculosis in each case constituted a true personal injury, as each one followed a fairly serious accident, usually involving the chest. On the other hand, there were 20 cases in which there was no relation between the accident or occupation and the disease. In fact in 14 of these no tuberculosis was found, the correct diagnosis being various other bronchial and lung conditions. One claimed glass dust hazard, but investigation showed such to be practically im-

possible. One claimed soapstone dust hazard, but no lung trouble was found, nor did the hazard seem appreciable. One claimed sulphuric acid fumes as a hazard, but investigation showed no evidence of such fumes although the acid was used. Another claimed dust from copper wire, but investigation showed no evidence of any dust whatsoever. Another claimed dust from a belt of sandpaper where it was found that protection was good, the amount of dust small and the periods of exposure very short. These cases show that tuberculosis is used as a convenient diagnosis on which to base claims for compensation in far too many instances.

Finally there was a third group of 14 border-line cases in which there was a possibility but not a probability of a just claim. (A detailed discussion of each of these cases is given.)—John B. Hawes, 2d, *Am. Rev. Tuberc.*, XVIII, 6: 767–775 (Dec.), 1928.

Some Measurements of the Transmission of Ultra-Violet Radiation through Various Kinds of Fabrics—It is necessary to examine black and white samples of the same cloth or fabric, to examine different kinds of weaves, and to determine the effect of dyes, before drawing conclusions regarding the transmission of ultra-violet rays. Even a slight yellowing with age decreases transmission. After deducting for the openings between the threads, the actual transmission through the threads, especially when dyed, is only about 5 to 10 per cent. As the threads usually occupy from 95 to 99 per cent of the total space, the transmission through a fabric material itself is usually insignificant. Therefore, transparency to ultra-violet radiation demands an open-weave fabric. On this basis fabrics made of silk and heavy wool yarns compare favorably with cotton and rayon. Evidently the question of the composition of the material for transmitting the ultra-violet has been overestimated. In passing through two or more layers of fabrics, transmission is greatly decreased.

The best reflector for sunlight is a closely woven white fabric, and such should be worn to protect the body from the ultra-violet rays in the tropics; a further protection would be to wear an inner garment of thin closely woven material of wool or cotton, dyed with a substance that absorbs ultra-violet rays. It was found that transmission through feathers was fairly high, even for colored feathers (tables and graphs accompany).—U. S. Bureau of Standards, *Journal of Research, Research Paper 6,* Aug., 1928, pp. 105–124.

Physiological Factors of Mine Ventilation—An historical resumé of recent investigations on silicosis is discussed in the first 5 pages, followed by a summary of recent investigations on high temperatures in which the importance of acclimatization and the protection against heat in deep mines is emphasized. Drinking water in the Witwatersrand contains a little lime juice and 7 gm. of ordinary salt per gallon, the tins being provided at all levels in the mine. The author discusses in some detail the methods of mine refrigeration, the findings of fatigue studies, and the relations of the "comfort zone." The article concludes with a summary of recent investigations of toxic gases found in mines, viz., oxygen, methane, hydrogen sulphide, and carbon monoxide.—R. R. Sayers, U. S. Bureau of Mines, *Circular No. 6089,* Nov., 1928, 16 pp.

The Ultra-Violet Transmission of Various New Glasses and Window Glass Substitutes as Compared with That of Common Window Glass—Ordinary window glass shuts out ultra-violet rays below about 310 $\mu\mu$. The U. S. Bureau of Standards finds that the

total transmissions of various glasses, when new, are as follows:

Trade Name	Per Cent Transmission
Fused quartz	92
Corex	92
Helioglass (Vioray)[1]	50
Vitaglass	50
Cel-o-glass[2]	20
Quartz-lite	5
Flexoglass[3]	1
Common Window Glass	0 to 5

1. Vioray is the foreign trade name for Helioglass.
2. This consists of a fine wire screen whose interstices are covered with cellulose acetate.
3. This is a loosely woven fabric usually covered with paraffin.

A sample of Vitaglass which had been in a hospital window in Rhode Island for a year was found to have a transmission of 25 per cent at 302 $\mu\mu$ (for thickness = 2.3 mm.). Helioglass was found to decrease in transmission at about the same rate. Corex glass appears to undergo no appreciable change in transmission when exposed to solar radiation, but a marked decrease when exposed to a quartz mercury arc. Cel-o-glass (cellulose acetate), which when new transmitted 30 per cent, after being exposed to daylight for 8 months transmitted only 5 to 10 per cent. Quartz-lite is not appreciably affected by sunlight, and only slightly by the quartz mercury arc. The thinner the glass in any case, the greater in general will be its transparency to ultra-violet rays (tables and one chart accompany). —U. S. Bureau of Standards, *Letter Circular 235* (3d rev.), Jan. 14, 1928, 6 pp.

Health and Recreation Activities in Industrial Establishments—This illustrated bulletin considers medical and hospital service for employes, sick leave with pay, vacations with pay, lunch rooms, indoor recreation, outdoor recreation, disability funds, group insurance, education, encouragement of thrift, administration of personnel work, and welfare work in company towns.—U. S. Bureau of Labor Statistics, *Bulletin No. 458*, Feb., 1928, 94 pp.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Synthesis of Vitamin B in the Rumen of the Cow—One of the authors in previous studies of vitamin B requirements disclosed that a calf will grow to maturity and produce offspring on a ration deficient in vitamin B complex. These observations led to the present study to determine the microörganisms in the rumen responsible for the synthesis of vitamin B complex. A pure bred heifer with a fistula 3½ inches in diameter in the rumen was the experimental animal. Alcoholic extracts from the rumen were taken 12 hours after feeding in portions of about 30 pounds and the material was incubated for 5 days at 37° C. in order to induce the growth of bacterial flora. Ethyl alcohol was added until approximately 70 per cent solution was obtained, which was filtered off and evaporated to dryness at 50° C., 1 gm. of the dry extract representing 25.4 gm. of the fresh rumen material. Experimental rats, 21 days old and about 40 gm. in weight, were fed a ration of casein, agar, olive oil, dextrine, dextrine rumen extract and McCollum and Simmonds mixture 185. Olive oil was incorporated in the ration in both normals and controls as the animals refused to eat the rumen extract because

of the butyric acid. In addition, cod liver oil was given to insure adequate vitamins A and D. Growth curves indicate the vitamin B complex in the rumen extract as the animals maintained good growth through an 8-week period, pointing to the synthesis of this complex in the cow's rumen. Microscopic examination of rumen smears showed neither acid-fast bacteria nor yeasts but a bacterium producing pale lemon-yellow colony which had not been previously described. The authors designate it "Flavobacterium vitarumen." Cultures of this organism were grown on suitable mediums, the growth washed off with sterile water and evaporated to dryness at 50° C. Similar feeding technic for the dried bacterial meal was employed as with the rumen extract. The chart indicates the satisfactory average growth of the rats. It is concluded that the vitamin B complex was produced in the rumen by bacterial fermentation and an explanation is offered as to why cattle may grow to maturity producing normal offspring and normal milk on an insufficient vitamin B ration.—S. I. Bechdel, Hannah E. Honeywell, and R. Adams Dutcher, *J. Biol. Chem.*, 80: 231 (Nov.), 1928.

The Manganese-Copper-Iron Complex as a Factor in Hemoglobin Building—Previous work has shown both manganese and copper effective in hemoglobin regeneration, and the high purity iron salts ineffective. The work here describes the results obtained by the addition of copper individually and in conjunction with the milk-iron diet. Four-week old rats were placed on whole milk diet until the hemoglobin content was reduced. Fresh cow's milk was fed *ad libitum* and the supplement added to the morning feed. Weight determinations were made weekly, and hemoglobin determinations were made with a Fleischl-Miescher hemoglobinometer from blood secured from the caudal vein puncture. A table is given showing hemoglobin growth data for rats on the milk-iron diet, the iron component being prepared from pure iron wire. Rats with high hemoglobin at the start utilized iron to some extent, but those with low hemoglobin could not utilize iron without the supplements. The milk-iron diet was supplemented with 0.05 mg. copper per rat per day in the form of the sulphate prepared from electrolytic copper. All animals showed increased hemoglobin in accordance with reports of previous workers. Milk-iron diet, supplemented with 0.1 mg. of manganese per animal per day in the form of the chloride from manganous carbonate, showed good growth and hemoglobin increase. Few failed to respond. When both copper and manganese supplemented the milk-iron diet the most rapid response in hemoglobin of any group was evident, confirming the suggestion of Whipple that the evidence points to a group of substances as the active principle.—R. W. Titus, H. W. Cave, and J. S. Hughes, *J. Biol. Chem.*, 80: 565 (Dec.), 1928.

The Mineral Constituents of Cranberries—Most of the nation's supply of cranberries grows in Cape Cod whose ground waters are noticeably high in chlorine effected by the proximity of the ocean. The mineral content of cranberries was studied on ½ barrel packages received at intervals during 1926. The air-dried, ground berries were analyzed according to the Methods of Analysis, Association of Official Agricultural Chemists, except that potassium was weighed as the perchlorate and iron was determined in samples which had not been cut, and had been ground in a porcelain mortar. A table is given indicating a relatively high content of manganese. Total ash is low, generally less than 0.2 per cent, with an alkalinity of about 2 c.c. normal NaOH per 100 gm. berries. A previous

paper by the author (*J. Biol. Chem.*, 79: 409, 1928) showed iodine content from 26 to 35 parts per billion.—Fred W. Morse, *J. Biol. Chem.*, 81: 77 (Jan.), 1929.

Antirachitic Potency in Relation to Volume of Oil in the Liver of the Cod—A variability in the antirachitic potency of cod liver oil in relation to vitamin A has been known for some time. As a rule, livers assayed have been those obtained in spring and summer months when they are fat, large in proportion to the weight of the fish, and contain a large amount of oil. In fall and winter the livers decrease in size as well as in oil content. The authors have had an opportunity to study a large number of cod in the Bureau of Fisheries, Woods Hole, Mass., throughout the year, and the records show that fish livers obtained at different seasons are of varying sizes and varying contents of oil. The livers were extracted with cold ether and, after evaporating, the remaining oil was assayed biologically by placing young rats on a low-phosphorus McCollum ration and noting the percentage of oil necessary to produce calcification within 5 days. On this method, a score of 100 was established for high grade medicinal cod liver oil and the accuracy was assured by the use of a large number of animals. Tables are given showing the potency of oils from individual livers compared with the weights of the livers, the amounts of the oil in the liver and the ratio between them. The low potency was 150 and the high 20,000. In the first case the liver oil ratio was 5 and in the latter it was 167, and in this instance the liver which weighed 45 gm. contained only 0.27 gm. of oil. The authors concluded that, for a fish of given size, antirachitic potency varies invariably with the oil in the liver, provided the livers are decreased in fat content and not increased. Segregating a number of the low potency and high potency and comparing them, it was found that in the high group the figure was about 30 times that of the low, but that the average weight of the livers is only about ⅓ in the former case of those in the latter, and the average quantity of oil about $\frac{1}{60}$ of those in the low group. The question as to how the antirachitic factor is soluble in liver fat when the liver fat is consumed is explained by the possibility of the oxidation of the liver fat in the course of starvation. In an attempt to answer the question as to whether this vitamin is synthesized by the liver, cod liver was divided into three different parts; one was extracted with ether, one boiled to destroy the enzymes and then extracted with ether, and to the third ergosterol was added as a substrate. Biologic assays showed no distinction in potency among the three portions of the liver, indicating no activation of the ergosterol by the liver cells. The authors, however, feel this is not conclusive in representing conditions *in vivo*. It is pointed out that cod liver oil may be 200 times as potent as that designated "high grade," and that such potent oil is very dark and obtainable only in very minute amounts.—Alfred F. Hess, Charles E. Bills, Edna M. Honeywell, *J. A. M. A.*, 92: 226 (Jan. 19), 1929.

Mucosus Organism from Suppurative Lesions of Rat on Diet Deficient in Vitamin A—Following the theory that deficiency of vitamin A causes such a reduction in cellular activity that it amounts to a deficiency of glandular activity and that this, in turn, brings about secondary changes, bacterial invasion and death, cultural studies of a group of animals dying from avitaminosis were made. Cultures were taken from the kidneys and from the ears of 31 white rats immediately after their death from experimentally pro-

duced deficiency in vitamin A. *Staphylococcus albus,* an organism of the Proteus group, and *B. coli* were isolated in a few cases but an encapsulated, Gram-negative, coccoid bacillus apparently belonging to the mucosus capsulatus group was isolated from 15 cases. In 12 of these cases it was the only organism present in the cultures. Morphological, cultural, serological and pathological studies of the organism showed it to be a Friedländer-like bacillus of low virulence for rabbits, guinea-pigs, mice and white rats when injected intraperitoneally or intravenously. Extending the study to other groups of animals, from 50 rats on A-deficient diets, representing 3 different stocks, 21 strains were isolated. In 13 normal rats, 3 rats on B-deficient diets, and 9 rats on D-deficient diets, all without obvious infections, cultures from the ears and nose failed to reveal the organism. Although obviously more frequently present in the suppurative conditions of the animal on an A-deficient diet, it is probably a secondary invader of mucosa of the respiratory tract, made suitable for its invasion by the dietary deficiency.—William L. Bradford, *J. Infect. Dis.,* 43: 407 (Nov.), 1928.

Thermophilic Bacteria in Canned Foods—The organisms described in this paper were isolated in the examination of 65 cans of food, including normal and spoiled corn, sound and "flat sour" peas, tomatoes, beans, pumpkin, meats, fish, evaporated milk processed cream and "swelled" canned fruits. Twenty-three cultures were isolated and studied in detail. These cultures were obtained from market corn and peas incubated at 55° C., from "flat sour" peas, and "swelled" cans of pumpkin. The remaining cans of normal and spoiled foods did not yield thermophiles. The cultures fell into 2 groups: 21 apparently closely related and probably identical strains; and 2 that corresponded with each other but not with the majority of those isolated. The minimal temperature for growth of the organisms studied was 42° C. and the optimum temperatures were between 55° C. and 62.5° C. At pH between 5.8 and 8.2 growth occurred within 18 hours at 55° C. regardless of the reaction. All the strains studied fermented dextrose with the production of acid but not gas. They also formed acid from various other carbohydrates. In studying the resistance of the spores to heat it was indicated that 17 hours at 100° C. was not sufficient to destroy the spores in the given medium with the given concentration of spores, which varied from 36,000 to 500,000 per c.c. as determined by the plate method. Sourness, with pH 4.7 to 5.5, was produced by inoculating peas and corn with organisms of the larger "flat sour" type group. The 21 organisms of this group which were identical and which were isolated from "flat sour" vegetables were found to resemble closely *B. stereothermophiles* Donk and were considered the cause of "flat sour" spoilage. The 2 remaining cultures seemed unlike the others and unlike any previously described in the literature. They were considered a new species and named *Bacillus pepo.*—Myrtle Shaw, *J. Infect. Dis.,* 43: 461 (Nov.), 1928.

Discontinuous Variation in the Virulence of B. aertrycke (Mutton)—It had been observed that different strains of *B. aertrycke* (mutton) showed a definite decrease in virulence when subcultured daily in broth. This change in virulence suggested the possibility of some bacterial dissociation resulting in the replacement of the original virulent organisms by variants much lower in virulence. Another possible explanation of this phenomenon was that the virulence of the constituent organisms was gradually falling, be-

coming evident only at a given point on the downward curve based on the four-dose technic used by Lockhart. In order to test which of these possibilities —if either—was true, a series of experiments was undertaken, including a repetition of Lockhart's experiments, testing, however, the virulence not only of the whole culture but also that of some of its constituent organisms. On the basis of these experiments the author concluded: (1) That a pure culture of *B. aertrycke* may contain individual organisms showing markedly discontinuous variations in virulence, when tested by intraperitoneal inoculation of mice. Side by side regardless of whether colonies were rough or smooth forms individual organisms comprising the parent strain showed marked difference in virulence, although otherwise indistinguishable from one another by the ordinary methods of examination; (2) That when a given strain comprises organisms showing discontinuous variations in virulence, the virulence of the entire culture is similar to that of the most virulent variants. While not entirely conclusive the experiments indicate that this proposition may be subject to definite quantitative limitations. It was observed that if even 10 per cent or less of the constituent organisms of a culture are fully virulent, the whole culture will itself prove fully virulent; (3) Whole cultures exhibiting a similar degree of virulence are not necessarily similar in constitution. In other words, the virulence of a culture of *B. aertrycke* in its entirety affords very little guidance to the virulence of the individuals present or to the proportion in which the variants are present; (4) There is no apparent basis of comparison to indicate any relationship between the possession of a type or group antigen and the degree of virulence of *B. aertrycke* (mutton); (5) There is no constant relationship between the virulence and the infectivity of a given strain of *B. aertrycke* when introduced directly into the tissues; (6) Daily subculture in broth of this organism with incubation either under ordinary aerobic conditions or in an atmosphere of 1 per cent or 21 per cent oxygen maintained by bubbling the gas continuously through the culture results in time in a complete fall in virulence. The evidence brought forward by the author indicates that it is wrong to regard a whole pure culture as a collection of homogeneous organisms. Any given culture consists of an extremely large number of individual organisms which vary in one or more respects. Side by side in the same pure culture there have been found virulent and entirely avirulent individual organisms. It is suggested that loss in virulence may be explained by replacement of virulent individuals of a culture by avirulent or weekly virulent organisms. —G. S. Wilson, *J. Hyg.*, 28: 295 (Dec.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

A Study of 370 Deaths of Primiparae—The problem of maternal mortality is such a pressing one, and so little is really known about the basic factors involved, that every death in childbirth should receive the most careful study possible. To individualize cases in this fashion is relatively expensive and the results thus far have yielded more chaff than grain; but by staggering the load among many health departments and other agencies, returns will undoubtedly come in time.

This study which Dr. DeKruif reports is an analysis of causes of death among a group of primiparae whose histories were investigated as part of a larger study of 984 deaths of mothers in childbirth, undertaken by the Massachusetts Department of Public Health. The data were obtained from the physicians who had charge of the patients and from hospital records.

The two principal causes of death among these primiparae were sepsis (primary and secondary) and the toxemias. Cesarean section leads as the method of delivery. This operation seems, however, to have been—with the exception of low forceps—the measure most favorable to the baby.

Other interesting facts brought out are: The toxemia group led as a cause of prematurity; there were 157 hospital booked, 119 hospital emergency and 80 home deliveries. Seventy-two per cent of these primiparae were operative cases whereas 53 per cent only among 614 multiparae were operative.

There was evident lack of prenatal care in 73 per cent of the cases. One-third had no prenatal care at all. It should be said, however, that in about one-third of the cases the cause of death had little or no apparent relationship to the prenatal care.—Mary DeKruif, M.D., A Study of 370 Deaths of Primiparae, *New England J. Med.*, Dec. 27, 1928.

Maternal Care in Berlin—According to recent reports, the city of Berlin endeavors to protect the health of its prospective mothers by means of 40 municipal centers for the care of pregnant women. These centers are staffed by gynecologists, graduate nurses and officers of the juvenile and public welfare departments.

The service offered here is free to all, rich or poor. No credentials of any kind are required. Among the types of service offered are: examination, medical advice, medical treatment, financial aid, legal information, accommodations before and during confinement, accommodations for mother and child, and nursing care at home.—Organization of the Care of Pregnant Women in the City of Berlin, Foreign Correspondence, *J. A. M. A.*, Dec. 29, 1928.

Maternity Care in the Australian Bush—For a number of years Australia has had a system of "maternity benefits," consisting largely of a cash subsidy at the time of confinement. Apparently nearly every mother of a newborn baby avails herself of this maternity benefit, so-called. This service, so far as one can judge by the figures, has had no appreciable effect on the maternal death rate of that country.

Another plan, this time directed toward the rural districts of the State of

Victoria, at least so far as the white inhabitants are concerned, has been in operation for more than 17 years. This consists of nursing, medical and hospital service sponsored by the Victorian Bush Nursing Association.

The report of this organization of its work during the 5 years ending in 1927 is most interesting. Twenty-two hundred and seventy-three confinements of white mothers were attended without the loss of a mother. The "bush" now has the lowest maternal mortality rate in Victoria, with the city of Melbourne—containing more than half the population of the state—holding the record for the highest rate. The average rate for Victoria is given as 5.58 per 1,000 live births.

It is natural enough that the association should attribute this favorable mortality experience "to the adequate training of both doctors and nurses and their excellent coöperation, insistence on continuous antenatal supervision, and properly planned, staffed and equipped hospitals to which all complicated cases are removed at the earliest moment." Whether this is the whole story or not is not so certain. We have yet much to learn regarding the part played by racial and other factors entirely apart from measures consciously directed against the maternal mortality.—Based on Note in *The World's Children*, Dec. 19, 1928.

Tonsillectomy in the United States—A recent editorial in the *Journal of the American Medical Association* discusses at some length various studies which have brought forward evidence as to the value of tonsil removal. It quotes a government report as estimating that about one-third of all operations since 1924 among the American urban population were for the removal of tonsils or adenoids.

The results of tonsillectomy may be viewed from various angles. The first question that comes to mind is, naturally—what is the effect on the incidence of rheumatism?

Kaiser reported on 48,000 school children, in 20,000 of whom the tonsils had been removed and in 28,000 of whom they had not been removed. He found the incidence of rheumatic fever, joint pains or growing pains and chorea slightly less in the tonsillectomized patients than in those whose tonsils had not been removed, but the difference was so slight as to be almost negligible. However, he calls attention to the fact that many with rheumatic manifestations in the tonsillectomized group had had their symptoms before operation.

Rheumatic heart disease was found in 450 of the 20,000 children with tonsils removed as compared with 817 cases among the 28,000 children not operated on.

Turning to other diseases, Collins and Sydenstricker from Hagerstown, Md., report a decrease in all respiratory diseases in tonsillectomized children; but this decrease was not great except in the case of tonsillitis and sore throat. Morbidity from non-respiratory causes was not noticeably lessened. On the other hand, during a 4-year period more scarlet fever, mumps, measles, whooping cough and chicken pox occurred in the tonsillectomized than in the non-tonsillectomized group. Diphtheria proved the exception with 4.6 cases per 1,000 in the non-tonsillectomized cases as compared with 1 per 1,000 in the children who had had their tonsils removed.

It is to be pointed out that two factors have to be considered in judging these figures—first, many tonsillectomies are imperfectly done, leaving a residue of tissue which renders the patient worse off than before; second, confusion is injected into the situation by the fact that there is as yet no uniformity regarding what constitutes a "normal" tonsil and what is the significance of an "enlarged" tonsil.—Tonsillectomy in the United States, Editorial, *J. A. M. A.*, Oct. 20, 1928.

Behavior Problems in Children under Three Years of Age—Preventive mental hygiene, we realize, has not kept up with the advancement in preventive medicine. The feeling that the specialist only can handle behavior problems among young children has been too prevalent. It is the family physician, after all, who has the opportunity to detect such problems, as he gets these young patients first. "The prevention of rickets with its subsequent malformation, which the orthopedist would have to correct, is analogous to the prevention of behavior disorders, whose subsequent maladjustments must be handled by the psychiatrist."

Mental and emotional life begin at birth. Behavior problems should be discussed with the mother as often as she visits the doctor regarding the physical care of her child. The earliest feelings of security and protection so necessary to the infant are apt to be prolonged by the fond parents and thus make trouble. Physical development is beyond the parents' power to delay and incoördination between physical and psychic growth results, which leads to behavior disturbances.

All ordinary reactions occur in all children to some extent, such as crying when left alone and refusing to go to sleep in the dark. It is only when such reactions are excessive and prolonged beyond the regular age limit that they may become difficult to overcome. A normal child meets new situations—weaning, toilet training, etc.—with comparatively easy adjustment, but the child who deviates from normal behavior will find it difficult and may show aggressive revolt by means of tantrums, crying spells, etc. The coöperation of all the persons in the child's environment is essential to effect a change of behavior. Thorough physical examination should precede all treatment, as abnormal organic conditions may be present.

The author illustrates her conclusions by interesting case stories.—Margaret E. Fries, M.D., *Arch. Pediat.*, Nov., 1928.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Another School of Nursing is Endowed—The endowment of $1,000,000 from the Rockefeller Foundation to the Yale University School of Nursing was announced in January, 1929.

The gift signified the success of an experiment carried on for 5 years to determine whether an educational program for nurses could be made comparable to that offered by medicine, law and engineering. Substantial financial backing assures the stability and continuation of this advancement in nursing education. (Of 116 students now enrolled, over one-half are college graduates.)

Outstanding features of the plan which has been endorsed by the Rockefeller Foundation are high admission requirements, emphasis on the study of fundamentals, and practical experience.

The Yale School of Nursing was founded in 1923 for the purpose of offering better educational opportunities for nurses, rather than increasing the number of graduates. Two years of college were required for entrance and the course included 28 months of practical and theoretical work under the direction of the New Haven Hospital.

A New Director for the National Organization for Public Health Nursing—The National Organization for Public Health Nursing has announced the appointment of Katharine Tucker, R.N., as General Director, March 1. Miss Tucker has been a moving spirit in public health nursing activities and has recently been the Director of the Visiting Nurse Society of Philadelphia.

Knowing as she does both the national and local aspects of public health nursing, Miss Tucker is uniquely fitted for the position. For several years she has served as a member of the Board of Directors and has also done field consultant work in surveying Visiting Nurse Associations.

What Every Nurse Should Know about the I. C. N.—Shall we see you in Montreal next July? The International Council of Nurses meets there from July 8 to July 13 for the first quadrennial convention since the one held in Helsingfors, Finland, in 1925.

Each American visitor or delegate to Montreal should have at her finger tips the history of this world-vide organization; otherwise, she will be confronted by enthusiastic delegates from foreign countries, for whom this is an open book, while for her it is still largely a matter of haphazard conjecture.

An article in the January issue of the *American Journal of Nursing* by the President of the International Council of Nurses, Nina D. Gage, R.N., contains this valuable information.

The International Council of Nurses was organized in London, England, July 2, 1899, and nurses from six different countries were listed as Foundation Members. The idea of forming international affiliations germinated at the time of the World's Fair in Chicago, 1893. At the same time a permanent organization for nurses, later known as the League of Nursing Education, was established in the United States. The objects of the International Council of Nurses are:

1. The advancement of the nursing profession by unity, thought, sympathy and purpose, in an attempt to improve the nursing care of the sick; to promote the health of the nations and to secure the honor and interest of the profession.

2. Self-government by the nurses in their associations, with the aim of raising the standards of education, professional ethics and public usefulness to their members.

3. The development of "the human being and citizen in every nurse," thus enabling her to bring her skill and professional knowledge to the many-sided service that modern society demands of her.

4. Provision for a means of communication and conference between nurses of various nationalities, and facilities for the interchange of international hospitality.

Admission to membership ever since 1904 has been through national organizations. Since then many countries have been admitted to affiliations, so that in 1928, 31 countries were represented.

All dues have been assessed on a basis proportional to the size of the constituent organization. Each individual member of the organization is taxed 5 cents in United States currency, as of January 1, each year; thus, if an association has 1,000 members, it pays $50.00 each year. The affiliated members represent more than 95,000 nurses.

Business is carried on by conference and correspondence between the headquarters in Geneva and various organizations. Conventions are held quadrennially, the program meetings of which are open to everyone. Each affiliated member association may send 4 duly accredited delegates, besides its president, to form with the officers and honorary officers the Grand Council, the voting body. American nurses are familiar with this kind of organization, as it corresponds to the House of Delegates of the American Nurses Association. The forming of friendships is a most important part of the convention.

The work of the International Council of Nurses is to draw together nursing councils from different nations; to disseminate among them professional information useful to all; to raise the standards of nursing education throughout the world; to offer assistance and advice to nurses; to arrange for subsequent meetings for the general consideration of important nursing matters and for the deliberation of questions of common interest and importance to nurses in every country.

There are committees on membership, program, arrangements, nominations, publications, revision, finance and nursing education. Many of us remember receiving with pleasure copies of a multigraphed bulletin, which Miss Reimann, Secretary of the Council, made so valuable. The popularity of that bulletin led to the indispensable magazine which has been issued quarterly since 1926.

Since 1925, Geneva, Switzerland, has been the headquarters of the International Council of Nurses (14 Quai des Eaux Vives). There, a nucleus of a small, but valuable, library is located. It is hoped that this will grow steadily and in the future become the center for research and study.

The progress and development of the International Council of Nurses (the first professional and scientific organization to become international) has been due to the vision and leadership of some of our ablest nurses. Mrs. Bedford Fenwick of England, the founder, has watched over the council from the beginning; Miss Breay was the faithful treasurer for 23 years; Miss L. Dock was the secretary for 23 years. Sister Agnes Karll exerted wide influence, not only in Germany, but throughout the world. Miss Nutting, as second chairman of the Education Committee, contributed the inspiration which has helped to raise the standards of education in many countries. Anna Maxwell of New York and Miss McMillan of Chicago have given valuable help and counsel. Baroness Sophie Mannerheim,

of Finland, served as president with a singleness of purpose that characterized everything she did. Miss Goodrich, Miss Noyes, Sister Bergliot Larssen and Christiane Reimann, the present capable, clear thinking, cosmopolitan secretary, are other leaders whom we have to thank for maintaining a truly international group and for piloting the organization through to safe waters.—The International Council of Nurses, *Am. J. Nurs.*, 29: 1 (Jan.), 1929.

Effect of the Grading Committee Report on Schools of Nursing—To quote Miss Hall, "I doubt very much if the first report from the Committee on the Grading of Nursing Schools has yet had any tangible effect upon the nursing schools in the country."

The report of the Grading Committee on Schools of Nursing given at Louisville indicated 4 almost overwhelming tasks for the nursing profession:

1. To reduce and improve the supply of nurses
2. To replace students with graduates
3. To help hospitals meet costs of graduate service
4. To get public support for nursing education

The idea of immediately reducing and improving the supply of nurses, both in small and large schools, is staggering. For a long time, the practice has been to let the nursing schools answer the needs of the hospital. Now the question of student enrollment must depend upon how many graduates may find employment and support. The problem of the training of the nurses, so vital to them, does not appear to be so important to many of the trustees of the hospital as the needs of the institution. Much educational work will have to be done before the recommendations of the committee are put into practice. Entrance requirements may be gradually raised, and this will improve the quality of the graduates.

"It is about as easy to put into practice the implications of the report as it is to enforce prohibition." Before either can be done, each endeavor must have the support of the public at large. The nursing profession cannot alone bring about the reform in nursing education.—Carrie M. Hall, R.N., Effect of the Grading Committee Report on Schools of Nursing, *Am. J. Nurs.*, 29, 2: 129 (Feb.), 1929.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

HONORABLE MENTION

For having "Contents" (at the front) and "Index" (at the back) in Biennial Report: to Bureau of Public Health, New Mexico.

For the title "Adventuring for Health" and the cover-page of the 1909–1929 report: to Welfare Division, Metropolitan Life Insurance Company.

For refreshingly unconventional design and color scheme in health posters: to Chicago Tuberculosis Institute.

To Health Department of Pasadena, Calif.—for including an index in its annual report.

To Tuberculosis and Health Society of Detroit and Wayne County, Detroit, Mich.—for table of contents in "Three Years at the Dubois Health Center" (a 31-page report).

MOTION PICTURES

A 14-page description of the Dr. Canti picture of cancer and radium effects, with details of the picture-making technic, is supplied by American Society for the Control of Cancer, 25 West 43d St., New York, N. Y.

A supplement to *Motion Pictures of the U. S. Department of Agriculture*, Washington, lists "How to Get Rid of Rats" (1 reel), and "Food Makes a Difference" (2 reels)—the latter picturing results of proper nutrition for children of preschool age, food laboratory tests of effects of foods, etc.

Possibilities in the use of amateur movies are well worth consideration by local health agencies. An important first step would be to get acquainted with *Movie Makers*, Amateur Cinema League, 105 West 40th St., New York, N. Y. *Sample free.*

IDEAS AND DEVICES

"Let's Fill the Gaps!" is the slogan of the Southside Health District, Dr. W. A. Brumfield, director, Farmville, Va. The 9 rural counties in the district are listed at the side of the District letterhead—with the names of the sanitation officer and the county nurse, or a blank line where one or both are not on the job. Dr. Brumfield is also head of Southside Hospital, constructed under the auspices of the Commonwealth Fund. Reported by C. E. Lakeman.

It does not look like a health department communication: "the Milwaukee Health Department's birthday letter to all 3-year-old children in Milwaukee and their mothers, calling attention to early correction of physical defects and to vaccination and diphtheria immunization, as well as early dental care. The letters are mailed by the nursing division so as to reach the mothers a day before the 3-year-old's birthday anniversary. Newspapers gave liberal space to the idea and a few of them reprinted the entire letter. The mailing started January 1, 1929. The largest daily in Milwaukee ran a picture of one of the first mothers to get the letter and her little daughter. They were selected because they were 'gold coast' residents, and their names helped to boost preschool child health work along." Reported by George A. Dundon.

There are 4 pages—on the first page: a wood-engraving type of picture of 5

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

men of the period when beards were beards—the caption being "As they wore them in anti-Gillette days"—and "Looking Backward" in the lower right corner. On the inside is "Yet Going Forward," with text about printing equipment. *Free* of De Vinne-Hallenbeck Co., 80 Lafayette St., New York, N. Y. Idea adaptable to annual report, annual meeting, and promotion projects.

A blotter with one edge accurately copying 6 inches from a foot-rule was distributed by a mimeographing shop.

"Social Hygiene" is on the tab of a 3 x 5 card. Below is a brief description of the American Social Hygiene Association, 370 7th Ave., New York, N. Y. At the bottom of the card: "Slip this card into your reference file." *Free.*

Bellevue-Yorkville Health Demonstration, 325 East 38th St., New York, N. Y., makes much use of the mimeograph—with colored paper and illustrations. Samples *free.*

For next summer: a street scene in red with "From blazing city streets . . . ." followed on 5th page by a country scene in green with ". . . to the cool green country." Inside: effective text on the summer services of Associated Jewish Charities, Baltimore, Md. *Free.*

REQUESTS

"Do people make use of the health information services offered in St. Louis, New York, and other cities? What difficulties have developed in handling such services?" Please address the editor.

"Can you advise us where it would be possible to obtain some illustrated charts suitable for lectures on oral hygiene. We would like to get some in which the illustrations would be of the cartoon type as well as some of a more serious nature. If there is any material of this description now being used in South America, we would be particularly pleased to get in touch with the source." Please tell the editor what you know.

TIMELY TOPICS

The Minnesota Public Health Association, St. Paul, Minn., issues a folder on "The 'Teen' Age and Its Tuberculosis Danger." It says: "One-fourth of all deaths in the 'Teen' Age are from tuberculosis. Twice as many girls as boys are patients in the tuberculosis sanatoria of Minnesota." Also: "Tuberculosis takes two 'Teen' girls for every boy. Fads That Kill: Reducing, Jazzy Life, Scanty Clothes, Lack of Rest." The editor fears that the full force of the special appeal is lessened by charting the leading causes of death *for all ages. Copy for 2 cents.*

"After All, This Is a World for Well People," by Wallace Myer. *Magazine of Business,* Chicago, Ill., Aug., 1928. 35 cents. Quotable on vacations and outdoor life for business men.

"Stews and Frys"—oysters and what the local health department does to protect the oyster eating public. Board of Health, Racine, Wis., Nov. 17, 1928.

TITLES AND PHRASES

"Even Your Friends Won't Tell You"—Tuberculosis and Health Society, 613 Locust St., St. Louis, Mo. Readable paragraph on getting a "big front."

"Select your doctor now and see him regularly"; "Most sickness is preventable."—Metropolitan Life Insurance Company.

VOLUNTEERS

How volunteers help at a health center—told in three short articles. In *Alameda County Public Health News,* 121 East 11th St., Oakland, Calif., Nov., 1928. *Free.*

"Volunteer Varieties: Various Vocations for Volunteers in Social Work"

—a 24-page booklet of the Volunteer Service Bureau, American Red Cross, 45 Newbury St., Boston, Mass. Under "Art," "Dramatics," "Health Education," and "Office Work" are jobs for volunteers in health education-publicity. The clever pen-line drawings on every page are suggestive for printed matter or mimeographing. Enclose 4 cents for a copy.

DATES AHEAD

March 31–April 7: National Negro Health Week. Address: Health Week Committee, Tuskegee Institute, Ala.

April: Early Diagnosis Campaign. Address: any tuberculosis association.

June 26–July 5: The next special opportunity for conference on publicity methods—at National Conference of Social Work in San Francisco. Address: Social Work Publicity Council, 130 East 22d St., New York, N. Y. Address: *The Survey,* 112 East 19th St., New York, N. Y., about special train starting from New York.

During March the Junior Red Cross will emphasize a swimming program to reduce deaths from drowning.

Last month was notable for the use of Valentine Day and the distribution of valentine greetings by American Social Hygiene Association. For your 1930 tickler of plans ahead.

Health conventions ahead should provide material for local newspaper use.

HOUSE ORGANS

"A Little Journey to the Clinic" and "A Farm Cure for Drug Addicts" —in two issues of *Community Fund News,* 51 West Warren Ave., Detroit, Mich.—interesting examples of descriptive writing. *Free.*

Kansas City's Health, Health Conservation Association, 1020 McGee St., Kansas City, Mo., has sent postal cards asking: "Do you read the bulletin? If not, why not? Do you pass it along for others to read? Do you think it has any educational value in the promotion of interest in health? How do you think it could be improved?"

Not a bit like a health department publication was the strikingly successful holiday issue of *Health,* New Haven Department of Health. The statistical data for the month were printed on a separate enclosure. The last page urged: "Give Health Books"—and give a dozen cover pages in color.

Bellevue-Yorkville Health News (325 East 38th St., New York, N. Y.): an excellent example of good use of the mimeograph and colored paper—legal size, one sheet, bi-monthly, addressed to neighborhood health workers and leaders in all coöperating groups. *Free.*

A list of fellows and a list of members of the A. P. H. A. from New Jersey who attended the Chicago convention were published in *Public Health News,* New Jersey Dept. of Health.

A brief sketch of a new school nurse in Indiana, in *Echoes* of Division of Public Health Nursing, mentions that the placement was made by Joint Vocational Service—a helpful way of emphasizing that service.

"This Month's Recommended Book —*Health and Wealth,* by Louis I. Dublin—Now at the Public Library." This was displayed in a box in the center of a page in *Health,* New Haven (Conn.) Dept. of Health.

CAMPAIGNS

Correction: The Early Diagnosis Campaign will be held during April—not in March as previously announced. Moral—but not an excuse for making the error: Put the date of campaigns (and of conventions and other coming events) on all printed mention of the same—and at some prominent place in every issue of your house organ or other periodical. We believe this will save time and avoid errors.

A campaign to reach 8,000,000 women with its message is being conducted by the American Society for the

Control of Cancer, 25 West 43d St., New York, N. Y. Leading national organizations of women are coöperating. State and local health agencies are afforded a special opportunity for approaching women's organizations in this connection since more women than men die of cancer.

" A baby hunt " was one of the forms of celebration of May Day reported by the American Child Health Association conducted in Missouri to secure the examination and registration of all children in the state.

" The Bridgeport Cancer Campaign " —description of preliminary steps, use of radio, printed matter, etc. " The total cost of the campaign, aside from the literature, was $596. Of this amount, $400 was expended for stenographic services."—*Campaign Notes,* American Society for Control of Cancer, Nov., 1928.

REPORTS

" Dividends in Don'ts " is a 12-page booklet " summary of achievements for 1928 " of American Social Hygiene Association. Illustrates how a few paragraphs can tell about extensive projects. *Free.*

When you wish to prove that all public department reports are not uninteresting, refer to " Human Dividends," annual report of Commissioner of Public Welfare of Westchester Co., East View, N. Y. *Free.*

" Different persons informed," " Different persons served," and " Kind of service rendered or arranged for," are headings in the quarterly service report of the Rochester Tuberculosis and Health Association. Every item under the headings is divided between children and adults, with the total. This 8-page mimeograph report *free.*

" Publicity Did It " tells of the successful use of a report on sanitary and working conditions in candy making in New York, whereby the New York Consumers League emphasizes the " White List " over the " Black List." *Better Times,* 151 Fifth Ave., New York, N. Y., Jan. 7, 1929. 25 cents.

Now that many are struggling with annual reports it will be good to look up " Graphic Presentation of Public Health Nursing," which includes " How to Make Convincing Charts," by M. A. Burgess, *Pub. Health Nurse,* Aug., 1926. Get reprint for 10 cents from *Public Health Nurse,* 370 7th Ave., New York, N. Y. Applies to other fields than nursing.

TELLING TITLES

" Eye Aches and Eye Fakes "—*Hygeia,* Dec., 1928.

" Masked Riders · Menace " (" the battalions of disease ")—press release of New Jersey Tuberculosis League, 21 Walnut St., Newark, N. J.

" Silent Death " (carbon monoxide) —press release of Board of Health, Racine, Wis., Dec. 1, 1928.

REGRETTABLE BUT TRUE

That a Christmas seal order form, issued in a large city, had all of its more than 80 words in capitals or small caps—and three lines in 6-point type in red! Larger type is needed for legibility's sake when red ink is used—and all capitals are necessarily less readable than lower case.

That educational material of a high order of interest and value should appear, month after month, in a health department house organ set in 6-point type *and* in lines nearly 4 inches long! Happily it is not so bad as it could be —the lines are separated by leads.

EDUCATIONAL MATERIAL

" A Guide to Balanced Meal Planning," National Dairy Council, 307 North Michigan Ave., Chicago, Ill. Sample *free.* A 9″ x 7″ card, punched for hanging. One side: classified lists

—include daily at least one from each column, with diet for 3- to 7-year old child. Other side: daily menu suggestions, with foods for adults only, and foods for 3- to 7-year old children.

"Buying Health," *Saturday Evening Post* editorial reprinted in neat 4-page folder. Emphasizes "county full-time health unit." *Free.* State Charities Aid Association, 105 East 22d St., New York, N. Y.

PRINTED MATTER

If you are about to change your street address, a bright idea may result from seeing the recent announcement of the Children's Welfare Federation, 244 Madison Ave., New York, N. Y., that "We Are Moving Uptown."

"The Sign on Your House" is the cover page title of a 4-page folder. It is a happily phrased explanation of the meaning and importance of quarantine. By all means get a copy from Board of Health, Racine, Wis.

"Your Friend the Doctor"—a 4-page folder explaining "when you need a doctor," the kind of doctor to beware of, and "how to choose your doctor." Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

The Tennessee Tuberculosis Association wished to submit a collection of solid facts to its committees and helpers throughout the state. Under the heading, "Facts in Regard to Tuberculosis in Tennessee," the copy was printed on the Association letter-head (bearing a Christmas seal) and two attached blank sheets. The copy was set in two columns to the page. The form made the material about as readable as is possible. Cost, 1½ cents a copy—sample *free.* Mailed in No. 10 envelopes this memorandum form seems more effective than would have been an unillustrated booklet with enough pages small enough for envelope enclosure. The editor would like to see more experiments with the memorandum form for presenting facts and arguments to select groups.

Several attractively planned and well-printed folders come from the Illinois Society for the Prevention of Blindness, 203 North Wabash Ave., Chicago, Ill. In one the "Suppose Nobody Cared" theme is applied to the current activities of the society. But we do wonder if they tried to adapt their illustrations to dull finished paper before accepting such shiny paper stock. A blotter has good text and is well laid out—but it will blot only on one side. The Christmas appeal letter gains in white space by having the lists of names and other letterhead detail on the lower third of the back of the letterhead. The sheet being folded twice for a No. 10 envelope, this letterhead information faces the recipient as he unfolds the letter. (It takes so many words to state a very simple fact.)

LEAGUE OF NATIONS NEWS

C.-E. A. WINSLOW, DR. P. H.

THE Second International Conference on sleeping sickness convoked by the Council of the League of Nations was held in Paris, November 5–7. It considered the report of the League of Nations International Sleeping Sickness Commission and suggested a system of administrative control of trypanosomiasis based on enumeration of native population in infected areas, adoption of an identity book or card for each native containing particulars as to health which would serve as a medical passport, establishment of boundaries at which medical authorization should be obligatory for passage, the establishment of observation posts for medical examination and, in extreme cases, the evacuation of heavily infected zones and the transportation of the population to a more favorable location. An exhaustive program of desirable research was laid down, dealing with natural immunity, spontaneous cure, and acquired immunity in man, with natural reservoirs of trypanosome infection with the relation between the different species of trypanosomes, the progress of infectivity during the cycle of transmission, and the value of various therapeutic agents. It was recommended that the health organization of the League of Nations should appoint a small expert committee to coördinate work done by various laboratories along these lines. The recommendations of the conference were approved at the 53d Session of the Council of the League at Lugano, December 11.

At this same session of the Council of the League, there was approved the program of the Health Committee for coöperation with Latin American countries involving the technical work of a specially organized leprosy commission and the continuation of inquiries at present being made in regard to infant mortality in Argentina, Brazil, Chile, Uruguay and other Latin American countries.

At a later session of the Council, the request of the Greek Government for the aid of the Health Committee in the reorganization of public health work in Greece was considered and cordially approved. Haven Emerson, M.D., has been asked to serve as a member of the special committee which will be sent to Greece to study the local problems and to aid in the development of the new program.

BOOKS AND REPORTS

Whither Mankind. *A Panorama of Modern Civilization. Edited by Charles A. Beard. New York: Longmans, Green,* 1928. 408 pp. Price, $3.00.

Readers of this *Journal* may be interested, even excited, mildly, to learn that the destination of mankind has finally been decided. Although the somewhat confused modern era is distinctly a machine age, subservient to science, it seems that we are, nevertheless, more spiritual, and that we are headed toward a period when collectivism and coöperation will supersede individualism, without, however, destroying independence and creative efforts.

Such is the trend of civilization, according to Professor Beard, who concludes this symposium on the destination of mankind with a sesquipedalian epilogue in which, using words seemingly averaging not less than six syllables, he informs us of the goal toward which he believes the other seventeen eminent contributors have headed us.

These celebrities, garnered from all over the world, discuss in an interesting if erudite manner the progress and ultimate position of such matters as Science, Business, Labor, Law and Government, War and Peace, Health, the Family, Race, Religion, the Arts, Philosophy, Play, Education, and Literature. Perhaps the most entertaining of the essays is that by Hendrik Willem van Loon on Ancient and Medieval Civilizations. There are several competitors for the one which is the least interesting.

Of special significance is the chapter on Health by Professor C.-E. A. Winslow, in which he explains brilliantly how the successful efforts of the sanitarian to prolong life and prevent disease have contributed to human progress, not by producing a race of weaklings but by accomplishing a gain in human quality as well as quantity. Another interesting chapter is that on Race and Civilization by George A. Dorsey, not because of the actual value of its substance, which is questionable, but because of the delightfully belligerent attitude with which he attempts to dispose of the so-called Nordic myth.

This book, written by a galaxy of eminent philosophers and savants, all of whom have had much literary experience, is a liberal education. Anyone who wishes to stimulate his mind with the most advanced thought on the most important integral features of modern civilization would do well to add this scholastic treatise to his reading list. It is, incidentally, well printed, and contains a number of rather bizarre illustrations.

JAMES A. TOBEY

Some Problems of Longevity—*By Frederick L. Hoffman, LL.D. New York: The Spectator Co., 1928.* 190 pp. Price, $6.00.

The question of longevity is always interesting. Most people are afraid to die, and as drowning persons will grasp at a straw, so they reach for anything which holds out even the remotest promise of prolonging life on earth.

Dr. Hoffman, whose high standing as a statistician is international, has given us an interesting book made up of thirty-five short chapters. Most of these give statistics regarding various ailments which shorten life. The chapter on suicide, which the author confesses is an unsolved problem, is an interesting preachment. Service in the army and navy is clearly shown to be conducive to long life, though it must be remembered that those entering are

carefully selected individuals. The suicide rate of army officers is astonishing.

The chief criticism that can be made of the book is that apparently some time elapsed between the preparation of the manuscript and its publication, since many of the figures given are not up to date. In the discussion of cancer, on which the author has already given us a most notable volume, he has unfortunately adopted theories for which there seems to be no ground. The statement that " white bread is so completely devitalized that it serves no genuine food requirement whatever " is wrong on the face of it, since the caloric value of such bread is high. In this idea, as well as the further conclusion that its use results in obscure bodily ills, which in turn may lead to precancerous conditions, the author is under the influence of Sir Arbuthnot Lane, which is further reflected in his advice concerning prevention.

In the discussion of leprosy, no mention is made of the great improvements in the administration of chaulmoogra oil due to the isolation of the ethyl esters by McDonald and Dean, nor of the number of patients being discharged as cured or arrested cases from the Carville leprosarium.

There is nothing in the make-up of the book which seems to warrant the price of $6.00. The print is small, but the paper is light and has a mat surface. There are no illustrations.

M. P. RAVENEL

The Basis of Breeding—*By Leon F. Whitney. New Haven: E. C. Fowler, 1928.* viii + 260 pp., 101 figs. Price, $3.00.

This is a book by a practical breeder of dogs who has a familiarity with the biological principles of the hereditary mechanism and with the structure and physiology of the reproductive system. It is written from the standpoint of the layman rather than the specialist. Though not free from technicalities, these have been reduced as far as feasible in the interests of simplicity of presentation. The text is divided into two parts, the first dealing with the hereditary basis of breeding and the second with the physiological basis. In the first part one finds chapters on such subjects as what does blood tell, the cause of sex, Mendelism, selection, pure lines, unmasking defects, inbreeding, prepotency, and breed improvement. In the second they deal with the reproductive systems, the mating cycle in man and domestic animals, birth, and sterility. There is a closing chapter with a long list of questions raised by the discussions, with references to the pages where appropriate answers will be found. The index also is very complete.

The book is very readable, full of interesting facts and much that is new regarding the breeding of dogs. It is a fresh and interesting treatment of a much discussed subject and a welcome and distinct addition to the literature of breeding.

Public health laboratories which rear their own animals will find it a valuable aid, since it deals not only with dogs, but also with rabbits, mice and guinea pigs.

C. A. KOFOID

Your Heart and You—*By Robert William Langley, M.D. Los Angeles: Wetzel Publishing Co., 1928.* 59 pp. Price, $1.50.

This short book, intended chiefly for those who believe themselves to be the victims of heart disease, covers the ground in a satisfactory manner. The causative relationship of rheumatic fever to heart disease is recognized, but is not sufficiently stressed, and is entirely omitted from chapter XII, " Facts about Heart Disease," in which it could well find a place.

The printing, paper and illustrations are good.

M. P. RAVENEL

Transactions of the Fifth Annual Meeting of the American Child Health Association—*New York: American Child Health Association,* 1928. 333 pp. Price, $3.00.

The transactions contain the papers read at the joint sessions of the Child Hygiene Section of the American Public Health Association and the American Child Health Association, when these two organizations met in Chicago, October 1928, for the Fifty-seventh Annual Meeting of the former association and the Fifth Annual Meeting of the latter. Papers read before the technical sessions of the American Child Health Association are also included. The most recent conclusions of authorities on maternal mortality, school health education, infancy and preschool problems, school medical and nursing service, dental health education, and objective standards in health education are presented in this volume.

Employment of the Tuberculous—*By Alice Campbell Klein and Grant Thorburn, M.D. New York: New York Tuberculosis and Health Association.* Price, $.50.

A 3-year experiment in "medically supervised employment for patients recovering from tuberculosis," conducted by the New York Tuberculosis and Health Association, is summarized in a book just published by the association. The study concludes that "there are no industries in which *all* jobs are suitable for the tuberculous, and on the other hand there are only a few industries which have *no* jobs suitable for the tuberculous."

Another conclusion derived from the experience with more than 900 former tuberculosis patients is that it is not feasible to list trades and jobs which are suitable for the tuberculous, but rather to list the factors to be avoided, and those to be sought, in selecting work for such persons.

The book contains a detailed report of this, the only such experiment thus far conducted under the intense, active and natural conditions of work in offices, stores and factories in New York City. The expenses of the experiment were borne jointly by the New York Tuberculosis and Health Association and the Laura Spelman Rockefeller Memorial. Copies are being distributed by the National Tuberculosis Association, 370 Seventh Avenue, New York, N. Y., at 50 cents a copy. There are 1,150 books ready for distribution.

How to Enjoy Health—*Counsels and Maxims for the Healthy Life—By Claude Lillingston, M.D., and Norah Hill, A.R.R.C. With Preface by Sir Squire Sprigge, M.D. London: Hodder and Stoughton,* 1928. 287 pp. Price, $1.00.

This little book is the conjoint work of the well known editor of *The World's Health* and his assistant editor, one a physician and the other not.

The authors state in their preface that they have checked each other's work, Miss Hill having prevented the too great use of technical language and "scientific jargon," and Dr. Lillingston having verified the facts collected by Miss Hill.

There are thirty-seven essays, all of them articles originally published in Red Cross journals, many of which have been translated into several languages. The three characteristics of the book which impress one are accuracy, common sense and humor. It is something of a relief to get away from the cut and dried formula which most books on health follow. The history of the essays already given shows that the book is intended for the public. None the less, physicians and public health workers can read it with pleasure and profit.

The printing is exceptionally good, and the binding, though light, seems adequate for a book of its size.

M. P. RAVENEL

The Home Dietitian—*By Ella Mae Ives (3d ed.)—Philadelphia: David McKay Co.*, 1928. 710 pp. Price, $2.50.

The book is primarily a volume of recipes for all occasions, offering variety and tempting experimentation. However, the title of the book is justified by a few scientific introductory pages to sections written by authorities on diet for adults and children, food classifications and food quantities.

Harvard Health Talks, 9. Pneumonia—*By Frederick Taylor Lord, M.D. (rev. ed.). Cambridge: Harvard University Press, 1929.* 142 pp. Price, $1.00.

Since the first edition, which appeared in 1922, notable advances have been made in the study of pneumonia, particularly in regard to the types of the causative organism and the specific treatment by serum, its uses and its limitations. The refining and concentration methods of Felton are considered.

Written, as it is, by a well-known authority, this new edition is welcome.

M. P. RAVENEL

On the State of the Public Health. *Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1927—London: His Majesty's Stationery Office,* 1928. Price, 2 s. 6 d.

The annual reports of Sir George Newman are in a class by themselves. We look forward to them with eagerness. The present volume strikes us as being even better than its predecessors. Though the material applies particularly to England, the fundamentals are applicable to every part of the world—indeed, there is a section devoted to international health, and there are other chapters on epidemiology, foods and the laws concerning the importation of foods, which are directly international in their character.

While it is hard to select chapters for special mention, we believe those on tuberculosis and the relation of food to health and disease are of particular value. The whole report is written in the clear and convincing style characteristic of the author.

M. P. RAVENEL

Proceedings of the National Conference of Social Work—*Chicago: University of Chicago Press,* 1928. 670 pp. Price, $3.00.

The proceedings of the fifty-fifth annual meeting of social workers held in Memphis, Tenn., May 2–9, 1928, contain an interesting section in health, the papers of this section having been contributed by national figures in the health and social work field. The proceedings are divided into sections dealing with children, delinquents and correction, the family, industrial and economic problems, neighborhood and community life, mental hygiene, organization of social forces, public officials and administration, the immigrant, professional standards and education and educational publicity.

Topical Sources for Personal Hygiene Applied—*By Jesse Feiring Williams, M.D. Philadelphia: Saunders, 1929.* Price, $1.00.

The books on hygiene by Dr. Williams have attained a position which is their just due. This source book, which refers particularly to "Personal Hygiene Applied," will aid teachers in formulating courses and in designating literature for term reports.

The book is well put together, and can be recommended to those engaged in the teaching of hygiene and public health.

M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Anderson County, S. C.—The 1928 report of this county health unit, which serves 80,000 people, indicates that an antidiphtheria campaign reached 3,500 children, while 6,961 typhoid inoculations were given. About 90 per cent of the school population have been vaccinated.

Interest was stimulated in the examination of children of preschool age, and summer round-ups were conducted in four schools. Special written instruction in proper diet and in needed corrections were given the mothers, and each child was given a milk bottle weight tag.

Child health conferences are held, midwives are encouraged to send their patients to prenatal clinics, and classes of instruction are conducted for midwives. Considerable work has been done in health education, through the schools, the press, the county fair and exhibits, including the distribution of nearly 25,000 pieces of health literature.

Kentucky—The December bulletin of the State Board of Health contains an analysis of vital statistics for the state for 1927, including death rate tables for 5 years and birth rate tables for 2 years. A general death rate of 10.8 for 1927 (9.8 for white and 19.8 for colored persons) is recorded. An infant mortality rate of 62.3 in 1927 compares with a rate of 74.5 in 1926. Deaths of children between the ages of 1 to 5 years declined from 2,280 in 1926 to 1,614 in 1927. A birth rate of 24.1 for 1927 is noted. This is an interesting and comprehensive statistical report.

New Hampshire Tuberculosis Association—During 1927, there is reported a tuberculosis rate of 63 per 100,000 population—the lowest recorded for the state. This compares with an average annual rate of 118 in the decade preceding 1917, 89 in 1922 and 66 in 1925. It is gratifying to note that the clinics are gradually dealing with lessening numbers of far advanced cases. "The state-wide clinic, nursing and educational campaigns, the increasing coöperation of the medical profession and the public at large, are resulting in the early discovery of easily curable cases. From our clinic experience we know that the great majority of these cases do not develop into advanced cases, but under prompt treatment are cured."

Among the encouraging factors listed are the steady downward trend in the death rates and in the number of advanced cases, the increases in the number of arrested and cured cases, the widespread interest and sympathy of the people, and the complete state-wide organization of clinic and nursing service. One of the important discouraging factors is the occurrence of acutely active cases of tuberculosis in young people between 15 and 20 years of age, particularly among young women. "That this is due at least in part to under-nutrition is quite evident in some cases."

Connecticut—Another year without marked epidemics, except measles, is noted, and the coöperation shown by the physicians of the state is considered a major factor in control work. By means of leaflets, posters, illustrated lectures, moving pictures and exhibits, the department has endeavored to disseminate information on the promotion of health and prevention of disease. Among the exhibits were those at the State Fair and at the Sesquicentennial Exposition at Philadelphia. Attendance

at film showings numbered 109,062 in 267 places. There were 246 health talks given, with an attendance of 26,159. Including these activities, posters and exhibits, exclusive of leaflets, it is calculated that 212,900 persons were directly reached by the health education service.

The state reports for 1926 a birth rate of 18, a marriage rate of 7.7 and a death rate of 11.4, with a rate from puerperal diseases of 6.4. A special study has been carried out during the past 3 years of 370 diphtheria deaths in the state, or 85 per cent of the total deaths from this cause. During this time, 27.9 per cent of the diphtheria cases were under 5 years of age, but 53.2 per cent of the deaths were in this age group. In 39 per cent of the deaths the doctor was not called until the 4th day or later. None of these fatal cases had been immunized against diphtheria by toxin-antitoxin.

The report indicates that few public health activities have such an appeal as child hygiene.

Three out of every 100 babies born each year are now living who, ten years ago, would have been dead. If these were valued at $1,000 apiece, the profit for the year to health workers in the state may well be termed 866 × $1,000, or $866,000. A rather appreciable dividend to the onlooking world, not to mention the value of this saving to mothers and fathers.

The legislature has recognized the need for public health nursing in the state and passed a bill providing for state aid for these towns so that all towns having average receipts of not over $50,000 for the three fiscal years preceding are now eligible to ask the department for state aid.

What is the dividend in health for 1926? Applying the methods of calculation promulgated by the National Conservation Commission as was first shown in the 1921 and 1922 reports of this department, Connecticut saved $2,734,600 in preventing deaths of persons in the state who would have died if the disease death rates for the average of the years 1915–1919 prevailed today. . . . It would therefore appear certainly safe to say that the savings effected from lessened deaths and lessened cases of disease is at least twice the savings due to lessened mortality. From this it will appear that in the last 5 years there has been a total saving to the state of at least 28 million dollars.—
State Dept. of Health, 42d report for the year ending June 30, 1927.

Kansas—The 14th biennial report of the Kansas State Board of Health, for the period ending July 1, 1928, contains 252 pages of text, statistical and graphic material, including a table of contents at the front and an alphabetical index at the back. This is one of the best state reports of the year from the standpoint of arrangement, use of space and special features. One of the most creditable features is the statistical graphs and charts which have been carefully made and convey a message of progress in results of health work. Another attractive feature is the health posters reproduced from the drawings of high school pupils who engaged in a contest sponsored by the department in 1927 and 1928. The posters were judged by a committee composed of health officers and art editors.

An effective chart shows that about 75 per cent of the infectious disease reports are received during the first 6 months of the year, the season when acute respiratory infections are most prevalent, the highest percentage occurring in March, measles, chicken pox, and scarlet fever being most prevalent. The board of health has adopted the slogan " Diphtheria Must Go," and has instituted an intensive program. According to the Board of Agriculture, there were in 1927, 548,409 persons in the state under 20 years of age. Reported immunizations against diphtheria include 18.8 per cent of this number. Infant mortality has decreased from 87 in 1913 and 75 in 1914, to 54 in 1927.

A school for health officers and public health nurses was held in April, in

1927, and in 1928. These schools were made possible through the coöperation of the U. S. Public Health Service and the Rockefeller Foundation. In addition to the public health group, a number of physicians in private practice attended the majority of the sessions.

United Fruit Company—Abounding in attractive photographs of company hospitals in Costa Rica, Panama, Guatemala, Colombia and Cuba, followed by scientific papers, this 1927 report of 368 pages is worthy of study. Considerable progress is reported in the control of malaria, which is considered a major problem, as about 90 per cent of the sickness in camps was due to this disease. Efforts to destroy mosquito breeding places by filling, draining, and the use of Paris green and oil; treatment measures by the use of quinine; and attempts to destroy mosquitoes by insecticide sprays and other means are described.

Considerable space is given to discussions of different methods of use and dosages of the new drug "plasmochin." The drug is particularly effective in cleaning the peripheral blood of gametocytes, which are the adult sexual forms of malarial parasites that infect mosquitoes. Unfortunately, it occasionally produces toxic symptoms when given in large doses over a prolonged period. The report indicates confidence that its use can be extended to the treatment of camp cases in such doses as to be effective without causing serious results. A reduction of 28 per cent in the number of malaria cases treated in hospitals over the number of the previous year (11,141 cases) is noteworthy.

U. S. Children's Bureau—An enlightening report of 150 pages on the promotion of the welfare and hygiene of maternity and infancy has been prepared for the year ended June 30, 1927. Infant mortality rates for 1927 were lower than for 1926 in 30 of the 33 states for which figures for both years are available. At the close of the fiscal year all the states except three were cooperating under the provisions of the Sheppard-Towner Act, the exceptions being Massachusetts, Connecticut and Illinois. The appropriation under this act has been authorized for the fiscal years 1928 and 1929, and the original act ceases simultaneously with the appropriation on June 30, 1929.

The types of work undertaken in the states under the maternity and infancy act are quite uniformly educational. The personnel of the bureau or division administering the act is determined by the needs of the state and the size of its budget. Physicians, nurses, dentists or dental hygienists and clerks make up the major part of the personnel. Including state directors, 140 physicians on the state staffs gave full-time service. Additional physicians were employed to conduct child health or prenatal conferences and to do special work. For example, it is reported that New York State paid 209 physicians for occasional service.

Public health nurses were on the staff of every state bureau or division, approximately 770 nurses being employed during the year. In 43 states and the Territory of Hawaii, 200,223 infants and preschool children were examined by physicians, or advice as to their care was given by physicians or nurses, and in 34 states 27,377 women were given prenatal advice by physicians or nurses. Dental conferences were reported in 15 states to the number of 1,124, where 27,870 preschool children received advice on the care of their teeth, in addition to 1,664 expectant mothers.

Milbank Memorial Fund—The Milbank Memorial Fund report for the year ending December 31, 1927, is divided into three parts. Part one presents a 5-year review of the results ac-

complished in Cattaraugus County and in Syracuse, a summary of the 1927 grants, and an outline of the studies of the New York Commission on Ventilation. The infant mortality rate in Cattaraugus County has declined about 19 per 1,000 births in 5 years, and decreases are also shown in the age periods from 1 to 35. The mortality reductions have been chiefly in the communicable, respiratory, and digestive diseases, and in diseases of the nervous system. The annual death rate from tuberculosis has steadily declined, especially in the younger age groups. Likewise, in Syracuse, decreases in death rates are most pronounced among the younger ages, especially in regard to the communicable and digestive diseases. Tuberculosis, infant mortality, and diarrhea and enteritis among children under 2 years of age exhibited marked reductions.

The Milbank Memorial Fund appropriated $193,000 in 1927 aside from the $325,000 set aside for the New York Health Demonstrations. Among the enterprises to which grants have been made are the Committee on Cost of Medical Care, the International Conference of Social Work, the National Board of Medical Examiners, New York Association for Improving the Condition of the Poor, and the Judson Health Center. The studies on ventilation set up in 1926 in selected schools in Syracuse and Cattaraugus County were carried forward under the New York Commission on Ventilation. In Syracuse conditions were compared in modern steam heated, mechanically ventilated school buildings with those in old naturally ventilated buildings, with results indicating an advantage in the latter. One-room and two-room rural schools in Cattaraugus County were studied in connection with construction, heating equipment and air conditions in the classrooms.

Part two outlines the Rural Health Demonstration in Cattaraugus County, the Urban Health Demonstration in Syracuse, and the Metropolitan Health Demonstration in the Bellevue-Yorkville District in the city of New York. The year 1927 was the first full year of service on the part of the health center under development by the Bellevue-Yorkville Health Demonstration. However, 49,000 visits were made to the health center by residents of the districts, and 60,000 visits were made to persons living in the district. The following activities are carried on: a baby health station, chest clinics for adults and children, a preschool clinic, a venereal disease clinic for adults, a vaginitis clinic for young girls, a dental clinic, a weekly Mothers' Club, nutrition classes for boys and girls in connection with the chest clinic, and lessons in home hygiene and care of the sick. A study of the tuberculosis nursing service in the area, a survey of prenatal, infant and preschool health activities, and a survey of the nutrition needs of the district have been accomplished during the year, in addition to studies based on the records of medical inspections of 1,445 third grade school children in 1925–1926. Data have also been prepared and a report distributed as a basis for an accident prevention campaign.

Part three of the report is a financial statement of the Milbank Memorial Fund with a list of grants. The report as a whole consists of 109 pages and is well prepared, with an abundance of half-tones, charts and tables. An addendum gives the supervisory and operating organizations and personnel of the three New York Health Demonstrations.

Seattle, Wash.—The 1927 report of the Department of Health and Sanitation of Seattle is a well formed volume of 97 pages, with a good index. Seattle has a total land area of 58.56 sq. mi. and a water area of 35.91 sq. mi. The estimated population for 1927 was 375,300. The crude death rate was

9.51, a decrease of 0.82 over that for 1926, while the infant mortality rate for children under 1 year was 41, the lowest ever recorded in the history of the city. The tuberculosis death rate was 53.5, or 10.2 less than for 1926.

The program of the Child Welfare Division has been broadened along lines designed to reduce the incidence of preventable sickness and deaths among mothers and infants. Medical supervision has been placed under the management of the Seattle Pediatric Society in order that physicians highly trained in the requirements of child life might be brought in attendance at the clinics, a move which led to highly favorable results. Seven child welfare clinics are conducted at strategic points in the city, with an attendance of 5,569; and 11,174 visits were made during the year by child welfare nurses, 875 of which were first visits.

Six hundred and forty-eight cases of tuberculosis were under the observation of visiting nurses at the close of 1927. The visits during the year numbered 5,827, while 3,244 cases attended the tuberculosis clinics. The city's sanatorium, Firlands, averaged 202 cases in 1927. In addition to the care and treatment of patients, the policy at Firlands includes the training of the nursing staff so that better equipped nurses may be sent out into this field. A strong plea is made to remove positions at the sanatorium from the civil service list in order that employment may be given to those patients and ex-patients who are able to use it.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Industrial Vocational Guidance—A rather rambling discussion of the placement problems and mental hygiene of the employes of one large department store.

ANDERSON, V. V. Vocational Guidance and Mental Hygiene of Industry. Canada Lancet, 72, 1: 7 (Jan.), 1929.

Rural Tuberculosis Trends—A summary of recent researches in tuberculosis rates. From 1900 to 1916 the urban rate was twice the rural rate while from 1921 to 1926 it was only half again as high. It is hoped that the Cattaraugus County demonstration will throw some light on the reasons for the difference.

ANON. The Trend of Rural and Urban Tuberculosis Mortality. Milbank Quarterly Bull., 7, 1: 1 (Jan.), 1929.

Puerperal Mortality—A general review of maternal mortality statistics and a discussion of the causes.

BLAND, P. B. Puerperal Morbidity and Mortality. M. J. & Record, 129, 2: 83 (Jan. 16), 1929.

Chlorination of Water—A general discussion of the value of treating potable waters with chlorine and the methods by which the chemical may be added to the various kinds of water supplies.

BUNKER, G. C. The Use of Chlorine in Water Purification. J. A. M. A., 92, 1: 1 (Jan. 5), 1929.

Potency of Cod Liver Oil—The potency of cod liver oil varies inversely with the amount of oil in the liver. Oils may vary a thousand times in value.

HESS, A. F., *et al.* Antirachitic Potency in Relation to Volume of Oil in the Liver of the Cod. J. A. M. A., 92, 3: 226 (Jan. 19), 1929.

Health Publicity—A description of window displays used in drug stores of the Bellevue-Yorkville district.

CANDEE, M. D. Selling Health in Drug Stores. Survey, 61, 8: 487 (Jan. 15), 1929.

Undulant Fever—Serum agglutination tests for *Br. abortus* done on 1,100 specimens of blood taken from patients not suspected of this infection gave 63 positive reactions. The incidence of this condition demands more serious consideration than it has thus far received.

GLORDANO, A. S., and ABELSON, M. *Brucella Abortus* Infection in Man. J. A. M. A., 92, 3: 198 (Jan. 19), 1929.

Oral Typhoid Vaccination—Experiments are reported in which it was found that agglutinins and complement fixing bodies were produced as readily by the oral administration as the subcutaneous injection of typhoid bacterine.

HOFFSTADT, R. E., *et al.* Immunological Studies of Typhoid Vaccination by Mouth. Am. J. Hyg., 9, 1: 1 (Jan.), 1929.

Leprosy—An account of the disposition of cases committed to the Federal leprosarium. During the last fourteen years 48 patients have been discharged, 10 to suffer a relapse and be recommitted.

HOPKINS, R., and DENNEY, O. E. Leprosy in the United States. J. A. M. A., 92, 3: 191 (Jan. 19), 1929.

Epidemic of Poliomyelitis—An analysis of the relation between severity of symptoms and distribution in the 1927 outbreak of poliomyelitis in Massachusetts.

LEGG, A. T. An Analysis of the 1927 Epidemic of Infantile Paralysis in Massachusetts. J. A. M. A., 92, 1: 31 (Jan. 5), 1929.

Cancer and Tuberculosis—A study of a carefully controlled group leads to the conclusion " that there is a definite and marked incompatibility or antagonism between the two diseases, cancer and tuberculosis, of such sort that both occur together at the same time in florid activity in the same individual, only with great rarity."

PEARL, R. Cancer and Tuberculosis. Am. J. Hyg., 1, 9: 97 (Jan.), 1929.

Rickets and Infection—Rachitic rats exposed to the sun for 2 hours daily for 4 weeks were more resistant to infection than rachitic controls, probably due to the curing of the rickets by the sun.

ROBERTSON, E. C. A Study of the Effect of Various Agents, Chiefly Sunlight, upon the Susceptibility of Rachitic Rats to Infection. Am. J. Hyg., 9, 1: 75 (Jan.), 1929.

Malnutrition and Nervousness—Studies with experimental animals and clinical observations indicate a close relationship between malnutrition and nervousness. Forced feeding and rest reduce nervous symptoms.

SCHAM, M., and SCHAM, G. The Relation between Malnutrition and Nervousness. Am. J. Dis. Child., 37, 1: 1 (Jan.), 1929.

Allergy and Scarlet Fever—The reasons the rash and acute symptoms of scarlet fever are allergic are discussed in detail. The dissimilarity of diphtheria toxin and the toxic substance of *Streptococcus scarlatinae* is considered.

STEVENS, F. A., and DOCHEZ, A. R. The Relation of Allergy to Scarlet Fever. New York State J. Med., 29, 1: 22 (Jan. 1), 1929.

Progress in Health Education—A review of the history of the health educational movement and the present status of the work by federal, state and city health departments and the voluntary health agencies. Very good.

TOBEY, J. A. The Development of Popular Health Instruction. Hosp. Soc. Serv., 19, 1: 19 (Jan.), 1929.

Tuberculosis Case Finding by Nurses—A study of a large number of patients admitted to tuberculosis sanatoriums showed that few were discovered by public health nurses. The authors urge the more general employment of health visitors and more interest in tuberculosis on the part of those employed.

WILLIAMS, L. R., and HILL, A. M. The Public Health Nurse and Tuberculosis. Pub. Health Nurse, 21, 1: 4 (Jan.), 1929.

Vitamin Values of Fats—This paper summarizes the reasons for butter shortage in England and tells of the production of margarines as rich as butter in vitamins A and D reinforced by the addition of fish liver oil.

WILLIAMS, P. N., and MACLENNAN, K. Fatty Foods in Relation to Public Health. J. State Med., 37, 1: 32 (Jan.), 1929.

Posture and Health—The effect of posture on health and efficiency and methods of posture training are discussed.

TALBOT, F. B. Posture, Health and Efficiency. Pub. Health Nurse, 21, 1: 8 (Jan.), 1929.

Anti-tuberculosis Vaccination—Intradermal vaccination with Calmette's vaccine proved efficacious in the writer's experience. The treatment seems too heroic for general acceptance.

WALLGREN, A. Intradermal Vaccinations with BCG Virus. J. A. M. A., 91, 24: 1876 (Dec. 15), 1928.

NEWS FROM THE FIELD

THE MEDICAL COLLEGE OF VIRGINIA

THE Chemical Foundation, Inc., New York, N. Y., has made a grant to the Medical College of Virginia at Richmond to provide for the employment, during a 3-year period, of a full-time expert to enlarge the present program of research in chemistry as related to medicine, surgery and dentistry. The special laboratory for this work will also be enlarged.

OFFICERS ELECTED AT ELEVENTH TEXAS WATER WORKS SHORT SCHOOL

AT the Eleventh Annual Texas Short School for water and sewer plant operators, held January 14–22, at the Agricultural and Mechanical College and at Bryan, Tex., the following officers were reëlected: *President*, J. Z. Martin, Breckenridge; *First Vice-President*, W. H. Deaton, Waco; *Second Vice-President*, Bud A. Randolph, Houston; *Third Vice-President*, L. A. Grimes, Abilene; and *Fourth Vice-President*, J. R. John, Dallas. The following officers were newly elected: *Secretary*, V. M. Ehlers, Austin; *Treasurer*, E. G. Eggert, Austin; and *Editor*, Ella G. White, Austin.

Abilene, Tex., was chosen as headquarters for the next annual meeting.

HEALTH WORKERS OF SOUTH-WESTERN OHIO

AT a meeting of the Health Commissioners of the South-Western District of Ohio, on January 23, it was voted to enlarge the association to include the public health nurses and all health workers of the district. Therefore the name of the association was changed to "Health Workers of South-Western Ohio," and the following were elected officers for the ensuing year: *President*, Dr. Edward Blair, Lebanon; *Vice-President*, Mary Ewalt, Eaton; *Secretary and Treasurer*, Dr. C. J. Baldridge, Hamilton. The next of the quarterly meetings will take place in Greenville, O., April 10.

DR. KAMM RECEIVES AWARD

DR. Oliver Kamm, director of chemical research of Parke, Davis & Company, has been awarded the $1,000 prize by the American Association for the Advancement of Science for the "most noteworthy contribution to science presented at the annual meeting," which was held in New York in January. The award was announced on January 2 and was given in recognition of Dr. Kamm's work in investigation of ductless glands and his isolation of pituitary hormones.

APPROPRIATION FOR INFLUENZA RESEARCH

MILTON J. Rosenau, M.D., Fellow A. P. H. A., of the Harvard University Medical School, has announced an appropriation of $10,000 by the Metropolitan Life Insurance Company for research on influenza and methods of its prevention. Dr. Rosenau is head of this company's influenza commission, other members of which are: Edwin O. Jordan, Ph.D., Treasurer, George W. McCoy, M.D., W. H. Frost, M.D., William H. Park, M.D., and Lee K. Frankel, Ph.D., all Fellows of the A. P. H. A.

MASSACHUSETTS GENERAL HOSPITAL PROJECT

PLANS for the new hospital for people of moderate means are now being put into operation by the Massachusetts General Hospital. The contracts

amount to nearly a million and a half dollars, and the trustees are confident of raising the full amount of the necessary funds.

YELLOW FEVER IN RIO DE JANEIRO

NOT since 1908, when there was a campaign to eradicate yellow fever, has there been an epidemic in Rio de Janeiro, until last year in May when the disease appeared again, although occasional cases occurred in the interim. From May until the beginning of October 108 cases had been reported, according to a review of the situation by Dr. Clementino Fraga, Director General of Public Health of Brazil. The case fatality rate was 55.5 per cent, 33 per cent among Brazilians and 62 per cent among foreigners.

In his report Dr. Fraga states that the disease was in all probability imported from the northern states, "the means of communication of which with the capital are all the time becoming more rapid because of the introduction of aerial navigation and because of the increased maritime intercourse carried on by new lines of fast steamers."

The incidence was much greater among men (82 per cent of cases), especially in the two age groups 15–24 and 25–34 years. Barely 10 per cent of those attacked were under 15 years of age. Foreigners were conspicuously more affected. Ninety per cent of the cases were removed to hospitals and the others were cared for at home. Isolation of reported cases and other preventive measures were applied at the beginning of the outbreak.

Extending through an area of 220 to 275 yards from known or suspected cases, supervision was established and continued for periods of not less than 30 days. At the peak of the epidemic over 175,000 persons submitted daily to medical examination at the hands of 73 physicians, 31 visiting nurses, and 100 fourth and fifth year medical students.

The supervision of mosquito breeding places made it necessary to divide the city into 27 districts, and later the districts were divided into 10 urban and 3 suburban districts. More than 1,800 men were employed to cover the city in weekly house to house visits.

Data secured at the last inspection showed a *Culex* index of 2 per cent, which gave grounds for the conclusion that the *Aedes* index is most reassuring and that yellow fever will be quickly exterminated in Rio de Janeiro.

DR. KOFOID EXPLAINS CANCER FILM

CHARLES A. Kofoid, Ph.D., Fellow A. P. H. A., Professor of Zoölogy at the University of California, assisted in the first public presentation of the Canti Cancer Film, given in San Francisco, January 22, and in Berkeley, January 29, under the auspices of the University of California. Dr. Kofoid explained the film, which traces the the growth of the normal as well as the cancer cells and describes the effect of radium upon them.

A. E. GORMAN GOES TO WALLACE & TIERNAN COMPANY

ARTHUR E. Gorman, Public Health Engineer for the Chicago Sanitary District and formerly Chief Sanitary Engineer, Department of Public Works, Chicago Health Department, has become associated with the Wallace & Tiernan Company on sales promotion work. Mr. Gorman assumed his new duties January 1 and is located at the company's headquarters in Newark, N. J.

For six and a half years Mr. Gorman was connected with the U. S. Public Health Service, as Assistant and Associate Sanitary Engineer. He is a Fellow of the A. P. H. A., and has served as chairman of the Public Health Engineering Section and also as section secretary. He was convention manager of the 57th Annual Meeting of the Association held in Chicago in 1928.

TYPHOID CARRIER IN NEW YORK DISCOVERED BY NURSE

A DISTRICT nurse of the New York City Department of Health detected a typhoid carrier dispensing coffee in a restaurant and immediately reported the case to Commissioner S. H. Wynne, M.D. The Health Commissioner stated that the discovery of George Pappas, the carrier, had undoubtedly averted an outbreak of typhoid fever on the East Side of the city. Pappas, who had been previously warned not to handle foodstuff, was arrested and sent to North Brother Island, after a bacteriological test showed that he is still a carrier.

There are 208 typhoid carriers listed on the books of the New York City Health Department, and in more than 7 years only 2 have violated their paroles. The other violator is now a prisoner on North Brother Island also.

CUYAHOGA FALLS HONORED FOR CLEANLINESS

CUYAHOGA FALLS, O., has been awarded the honor for being the "cleanest city in Ohio" by the General Federation of Women's Clubs of the United States in a contest for conducting the best and most efficient clean-up campaign.

DENVER APPRAISES ITS HEALTH WORK

AT a dinner to which all persons interested in the progress of their community were invited, the Denver Public Health Council arranged a conference dinner January 30, when a report of the appraisal of the public health activities of Denver was given. The topics emphasized in the discussion, apropos of the report, were infant mortality, milk control, diphtheria, tuberculosis, and child health in Denver. The appraisal was made by the Denver Public Health Council assisted by the Committee on Administrative Practice of the American Public Health Association.

FOUNDATION FOR POSITIVE HEALTH

THE name of the Women's Foundation for Health, Inc., has been changed to Foundation for Positive Health, Inc., with headquarters at 370 Seventh Avenue, New York, N. Y. The name has been changed to embrace programs of positive health for both adult men and women. The officers of the Foundation are Martha Tracy, M.D., president; Mary E. Wooley, first vice-president; Lenna L. Meanes, M.D., medical director.

NEW YORK CAMPAIGNS AGAINST DIPHTHERIA

A CAMPAIGN for diphtheria prevention was launched January 11 in New York City, at a luncheon given at the Harvard Club by Thomas W. Lamont of J. P. Morgan & Company, who is coöperating with Health Commissioner S. H. Wynne, M.D., and his newly formed Diphtheria Prevention Commission.

Letters have been sent to physicians of New York asking them to urge their patients who have young children in the family to have the children immunized by the toxin-antitoxin treatment.

These letters to be sent out by the family physician are in the style of a diphtheria warning and bear the seal of the City of New York and of the Medical Society of the county in which the physician resides. The warning is as follows:

> The Department of Health, coöperating with the Medical Society of the County, urges me to write you to have your child protected against diphtheria at once.
>
> It is necessary to have all young children between 9 months and 10 years safeguarded in order that they do not catch this dangerous disease.
>
> Treatment is simple, painless, safe and lasting, and requires a few minutes each time of three visits.
>
> I urge you to bring your child to me without delay so that your child may be protected, and the Health Department's wishes carried out.

Editors and owners of local newspapers and the directors and representatives of several health organizations of the city were guests at the luncheon. The newspaper editors have formed a press club to direct and promote the publicity of the campaign and to popularize this phase of the public health program.

AMOY SEEKS HEALTH

UNDER the above title, a recent article in the *China Medical Journal* describes how the city of Amoy in the southern part of Fukien Province is developing public health work. The city of 2 or 3 square miles, on the Island of Amoy, has a population of over 180,000.

Now, after 5 years of labor, Amoy can boast of a model system of water works which is in excellent running order. The filter beds and ozonating plants are amongst the best in the world, and next to none in the Far East. The reservoir is located among the hills far away from danger of contamination. Even the conservative old gentlemen who make up the Board of Directors are firmly convinced that this pure water supply has saved Amoy from cholera, dysentery and typhoid. They are pleased to report that in spite of opposition on the part of uneducated persons, the financial return on their $1,000,000 investment is already proving to be hopeful.

The article reports on new roads, new settlements, a city park, ponds filled, and the beginnings of a health campaign in coöperation with the Council on Health Education of China.

PERSONALS

CHARLES V. CHAPIN, M.D., former president of the A. P. H. A., was re-elected Superintendent of Health, Providence, R. I., for a term of 3 years. Dr. Chapin has served in this capacity for 45 consecutive years.

DR. W. H. NEWCOMB has resigned as Director of the Morgan County, Ill., Health Department to enter private practice.

DR. F. B. DART has been appointed Health Officer at large of Baltimore, Md., to succeed Dr. Harry Linden, resigned.

DR. W. ALLEN ETHERIDGE, associated with the Baltimore Health Department since 1923, has resigned and his successor as supervisor of dental clinics is Dr. Morris Cramer.

DR. JOSEPH P. FRANKLIN, Director of the Bureau of Communicable Diseases, Baltimore Bureau of Health, has resigned to accept the position of County Health Officer and Deputy State Health Officer for Allegany County, Md.

DR. F. H. JOHNSON, Carrizozo, N. M., has been appointed Health Officer of Lincoln County to succeed Dr. P. M. Shaver, resigned.

DR. T. B. LYON, Raon, N. M., has been appointed Health Officer of Colfax County, N. M., to succeed Dr. H. W. Heymann, resigned.

DR. A. WILLIAM LESCOHIER has been appointed general manager of Parke, Davis and Company. From 1918 until 1925 Dr. Lescohier was in charge of the production of serum, vaccines, antitoxins and other biological products when he was made director of the Department of Experimental Medicine.

DR. JOHN E. MONGER, Director of Health, State Department of Health, Ohio, from 1923 to 1929, has resigned to become managing director of the United States Standard Products Company, which manufactures vaccines, serums and antitoxins.

KATHERINE TUCKER, R.N., has been appointed general director of the National Organization for Public Health Nursing. Miss Tucker has had a wide experience in the public health nursing field and resigned as general

director of the Visiting Nurse Society of Philadelphia where she served from 1916 to 1929, to accept the position with the national organization.

RALPH C. SWEENEY, Assistant Sanitary Engineer, Ohio State Department of Health since 1919, has resigned to become Sanitary Engineer of Toledo.

EDGAR SYDENSTRICKER has resigned from the U. S. Public Health Service where he had charge of statistical investigations, to become Director of Research, Milbank Memorial Fund.

DR. I. C. RIGGIN, Cincinnati, O., has been appointed Executive Secretary of the American Heart Association with headquarters at 370 Seventh Ave., New York, N. Y. Dr. Riggin was formerly Health Commissioner of Lorain County, O., and was Executive Secretary of the Heart Council of Greater Cincinnati during 1928.

DR. ERNEST W. CAVANESS has resigned as Commissioner of Health of Kansas City, Mo.

LOUISE STANLEY, PH.D., Chief of the Bureau of Home Economics, U. S. Department of Agriculture, has been chosen to represent the department on the American Standards Association.

DR. MERRILL E. CHAMPION, who for several years has been Director of the Division of Hygiene of the Massachusetts Department of Public Health, has resigned and is succeeded by Dr. M. Luise Diez of the New York State Department of Health.

DR. ARTHUR S. HARTWELL of Norwood, Mass., has been appointed medical examiner of the first Norfolk district.

DR. ANDREW L. WEST has been appointed Director of Public Health of St. Joseph, Mich.

DR. BRON D. BLACKWELDER has been elected Director of the county health unit at Natchez, Miss.

DR. J. A. JOHNSON has been appointed Health Officer of Olean, N. Y. Dr. Johnson was formerly Health Officer from 1916 to 1922.

DR. WILLIAM R. MAY, Amory, Miss., has been chosen to direct the Lincoln County Health unit.

DR. WILLIAM SCHROEDER, JR., has been appointed head of the Department of Hospitals of Brooklyn, N. Y. This new department is under the guidance of the Department of Health and of the Department of Public Welfare.

DR. THOMAS A. RATLIFF has been reappointed President of the Cincinnati Public Health Federation. Dr. Julien E. Benjamin has been elected Vice-President and Dr. Arthur C. Bachmeyer, Honorary Secretary.

DR. J. FORREST STULTZ has resigned as Health Commissioner of Champaign County, Ohio.

CONFERENCES

April 8–12, 13th Annual Clinical Session of the American College of Physicians, Boston, Mass.

April 22–26, Seventh Annual New England Health Institute, Hartford, Conn.

May 7–8, Association of American Physicians, Atlantic City, N. J.

May 14–17, American Psychiatric Association, Atlanta, Ga.

May 27–31, National Tuberculosis Association, Atlantic City, N. J.

June 13, International Hospital Congress, Atlantic City, N. J.

June 17–21, Annual Convention, American Hospital Association, Atlantic City, N. J.

June 24–28, American Water Works Association, Toronto, Can.

July 8–13, International Council of Nurses, Montreal, Can.

July 13–20, Fortieth Congress and Exhibition of the Royal Sanitary Institute, Sheffield, England.

July 17–August 13, Third Vienna Summer School, University of Vienna, Austria.

The Economics of Medical Service*

W. S. RANKIN, M. D., FELLOW A. P. H. A.

Director, Hospital and Orphan Sections of The Duke Endowment, Charlotte, N. C.

THE recent organization of the Committee on the Cost of Medical Care, representing the different viewpoints of a number of organizations with a kindred interest, emphasizes the timeliness of the present discussion and justifies, to a considerable extent, at least, this brief review of current thought.

In considering the economic factors of any problem, we are concerned with two fundamental conditions: (1) the cost of production, and (2) the purchasing power of the people.

The great majority of people have no direct concern with most of the misfortunes of life, with poverty, with penal institutions, with broken homes, but everyone, sooner or later, meets the problem of disease, the common misfortune of us all. Sickness and impairment constitute á problem so large as to touch every individual life, and so important in our political life as to be a matter of real concern to everyone who has risen to the level of citizenship.

The average individual between the cradle and the grave spends one-fortieth of his time in bed because of incapacitating illness. The average worker loses 2 per cent of his time, a fraction more than 7 days a year, because of incapacitating illness.

One-fortieth of the population is constantly ill to the extent of being bedridden. Extensive and reliable studies indicate that where there is 1 person incapacitated, there are at least 2 physically impaired to the extent of from 10 to 50 per cent of their efficiency, which is to say that for every 1,000 people there are 50 who suffer from prevalent and chronic diseases that completely incapacitate for but a small part

* Read at the Second General Session of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

of their duration, such as tuberculosis, cancers, heart disease, vascular diseases, chronic indigestions, gallstones and kidney stones, hernias, unrepaired injuries following childbirth, etc.

THE COST OF MEDICAL SERVICES

The annual expense to the people of the United States for medical services, if itemized and totalled, would read about as follows:

150,000 physicians, @ $3,000 per annum	$450,000,000
140,000 private duty nurses, @ $1,500 per annum	210,000,000
150,000 practical nurses, @ $1,000 per annum	150,000,000
100,000 attendants, @ $1,000 per annum	100,000,000
50,000 dentists, @ $3,000 per annum	150,000,000
7,000 hospitals, with a total of 860,000 beds	750,000,000
Druggists for medicines	700,000,000
25,000 healers, chiropractors, osteopaths, Christian Scientists, etc., @ $2,000 per annum	50,000,000
Grand Total	$2,560,000,000

The people of the United States, it will be noted, are paying for the treatment of disease not less than $2,500,000,000 a year, or ($2,500,000,000 ÷ 120,000,000 population) $20.83 per capita, or approximately $100 per family.

The average wage-earner's family, according to studies conducted by the U. S. Bureau of Labor Statistics, pays $60.39 a year for medical services. The average farmer's family, according to studies conducted by the U. S. Department of Agriculture, pays $61.60 a year for medical services. The average family represented in the clerical personnel employed by a large insurance company pays $80.00 a year for medical services.

OTHER AND LARGER COSTS OF SICKNESS

In addition to the expense for medical services imposed by disease, there is an estimated annual loss to the people of the United States of $2,000,000,000, as a result of decreased wage-earning capacity. And this is not all—there is a still further loss of permanently interrupted wage-earning capacity through postponable deaths, estimated to be $6,000,000,000, making the total annual cost of disease to the people of this country $2,500,000,000 for medical services, plus $2,000,000,000 loss in wage-earning capacity, plus $6,000,000,000 death losses—a total of $10,000,000,000 a year. The total annual income of the United States is about $90,000,000,000.

THE PURCHASING POWER FOR MEDICAL SERVICES

Any service which costs as much as medical care and which is so absolutely essential to both individual and national prosperity and happiness, raises at once the question of the ability of the people to

pay for it. The income of the people of the United States, according to Leo Wolman, quoted in *The Survey* for June 15, 1927, was as follows:

6 per cent of families, annual income in excess of $2,900
90 per cent of families, annual income under $2,000
67 per cent of families, annual income under $1,450

There is a gap between the cost of medical service and the purchasing power of a large percentage of American families. The width of the gap may be measured to some extent by the percentages of people who are able (1) to pay in full, (2) to pay in part, and (3) to pay nothing for medical care.

According to the U. S. Bureau of the Census, in a study of "Hospitals and Dispensaries" in the United States as of the year 1923, 49.7 per cent of patients treated in general hospitals were able to pay in full; 19.3 per cent of patients paid in part, and 31 per cent of patients paid nothing.

Compared with these institutional payments for the care of the sick, we have no such reliable data as to the percentage of the people who (1) pay in full, (2) pay in part, and (3) pay nothing for the services of physicians. It is reasonable to suppose that if we had such data, we would find the pecuniary relation of patient to physician very similar to that of patient to hospital. It is, therefore, reasonable to assume that approximately 50 per cent of the patients pay their physicians' bills in full, 20 per cent in part, and 30 per cent not at all.

Unquestionably, a large percentage of American people are not receiving the medical care that they should have, both as individuals and as units of society.

The gap between the cost of care and purchasing power is not due entirely to differences between the cost of service and the means for obtaining it. There is another factor in the situation too important not to deserve serious attention.

The expenses of being sick are unanticipated, appearing at unforeseen and irregular times, and are not like the expenses for food, clothing, shelter, etc., anticipated, appearing regularly and paid for in monthly accounts. If a family had its average annual cost for sickness of $60 to $100 a year apportioned and appearing at monthly intervals with the other family expenses, the problem would be met by a much larger percentage of people than can now meet it successfully. All too often the bill for sickness falls upon the victim in annual, biennial, or even quadrennial accumulations. When a family runs along for one, two, or three years, and then has a serious accident or illness, with a hospital bill, professional charges for surgeons and nurses

—an account of $150 to $300—its economic stability is seriously jarred and often shattered. For a large percentage of families—that 50 per cent of American families whose annual income is below $1,200—when the unexpected and accumulated financial burden of sickness arrives, there is, as Dr. Michael M. Davis aptly says, one of these alternatives: medical charity or financial tragedy. It is, then, not the amount, so much as the condition of payment of the account with disease, that rips the family purse.

How can buckle and tongue be made to meet? What treatment will improve or relieve this social abnormality? What remedies may be considered?

Is an attack from both sides of the problem, designed on the one hand to lower the cost of medical service and on the other to improve the purchasing power of the public for obtaining medical service, possible? Is such an attack practicable? Let us deal with the two questions separately.

CAN THE COST OF MEDICAL SERVICE BE LOWERED?

There are two ways generally conceded for lowering the cost of medical care. One way is by the prevention of unnecessary disease, and the other way is through the use of an organized medical service.

Prevention—A bare statement of the principle of the economy of prevention versus cure is quite sufficient. Illustration and arguments are unnecessary.

Improved Medical Service—A skillful physician costs the patient less than an unskillful physician. His diagnosis is more complete and accurate, his treatment more efficacious, the number of visits necessary fewer, and the cure more permanent.

An organized medical service, that is, a medical service in which the several more important branches of medicine are properly articulated, a service that consists of a group of physicians, a pediatrician, several general practitioners, an obstetrician, an X-ray and laboratory worker, and one or more nurses, is many times better able to diagnose and treat disease than an unorganized service consisting of physicians and specialists without any well conceived coöperative plan of work. Such an organized, well rounded, inclusive medical service lowers the cost of illness by shortening the period of time and decreasing the number of visits necessary for treatment, and affording a more certain and permanent recovery. But this is not the only advantage.

An organized medical service can be offered for financial returns considerably smaller than the cost would be if the patient obtained the same service from unrelated practitioners and specialists. An or-

ganized service makes possible economies which are not possible in an unorganized service. In an organized service less office space is needed than would be the case if the same number of physicians were working separately; economies in equipment are possible, one X-ray outfit, one laboratory, one set of obstetrical instruments, one set of sterilizers, serving where otherwise a multiplication of equipment would be needed; economies in personnel are possible, one bookkeeper, one collector, one nurse, one technician, where otherwise several would be needed.

A few examples of the efficiency combined with the economy of organized medical services will illustrate and substantiate the above statements.

The Cornell Clinic—The efficiency of the Cornell Clinic is attested by the fact that 3,500 physicians in the City of New York and its environs have referred 12,000 patients to the clinic in the last 6 years, and further, by the fact that 130,000 visits a year are made to the clinic by 21,000 patients; moreover, its attendance is constantly growing. The character of its professional work is, so far as the writer knows, not questioned.

The economy of the clinic is indicated in the ranges of its charges, the charges varying from $1.60 to $5.00 per visit, the average visit costing $2.39.

Harry H. Moore,[1] referring to the economy available through the Cornell Clinic, says:

> It is illuminating to compare charges made by the Cornell Clinic for an entire sickness or disability with charges made in private practice. A patient with a fracture of the lower arm pays at the Cornell Clinic for complete treatment, including X-ray, baking, and massage and 12 visits to the clinic, an average of $37.50. A moderate private rate for the same services is $100.
>
> The cost of service to 80 patients of the Cornell Clinic, many of them still under treatment, selected consecutively so as to include a variety of disease conditions, was ascertained to be $522.40. It was then found that the same services, if given by a general practitioner charging a minimum office fee, would have cost these 80 patients $1,182, and that if given by recognized specialists with medicine, X-ray and laboratory tests, they would have cost them $2,595.

Certain Universities—Through an organized medical service, some of our larger universities, notably the University of Michigan, the University of Minnesota, and the University of California, are able to render a thoroughly modern medical service, including hospital care, to their students for from $9 to $12 per student a year. It is admitted, of course, that the sickness liability of university students is considerably less than that of the general population.

The Endicott-Johnson Corporation—Its 16,000 employes and their

families represent a total population of probably not less than 60,000 people. The corporation gives to this group of employes and their families a medical service which includes the full-time services of 27 physicians, 3 dentists, 1 X-ray technician, 51 nurses, and 2 pharmacists, for an annual cost of $25 per worker, or at a cost of $6 to $7 per capita for the whole industrial population.

Roanoke Rapids, N. C.—This industrial settlement, composed of the workers of 5 cotton mills and 1 paper mill, gives a very modern, efficient medical service, including hospital care, home visits, and public health nursing, for $23.60 per family, or at approximately $9 per capita.

That the professional work of these organized services, as compared with that of unorganized services, is of a very high order, will be everywhere admitted. The leaders of the profession identify themselves with group practice, i.e., with organized medicine. When sick individually or when their families are sick, they resort to the use of an organized service. It is more efficient; it is more economical.

The merit and the future of organized medical services are indicated in the development of clinics. In 1900 there were 150 clinics in this country; now there are more than 5,000 in operation.

Unquestionably, one way to lower the cost of medical care is by improving the character of the medical service, and the first step in this direction is the establishment of a proper relationship between various medical specialties. The figures with reference to the development of group clinics are encouraging and indicate that professional leadership is handling this problem expeditiously and is not in any great need of outside assistance.

CAN THE PURCHASING POWER OF THE PUBLIC BE IMPROVED?

The point has already been made that if the average annual cost of disease and accident per family were evenly distributed over the months and years, it could and would be paid by many who, under present conditions, are unable to meet it.

A remedy for other large and unanticipated losses, which bring with them serious financial problems, has been found. In the unanticipated loss of the family of financial support by death, in the unanticipated loss of a man's business by fire, in the unanticipated liabilities of estates through accidents and suits, we take advantage of the insurance principle. The insurance principle avoids unanticipated and serious financial losses by anticipating and apportioning them over long periods of time and over large groups of the people. Total burdens that crush are borne easily when divided.

Roanoke Rapids is a splendid example of the application of the insurance principle in the anticipation and apportionment over many weeks and large numbers of people of the cost of sickness. The mill worker takes care of his family by the weekly payment of 25 cents, and so avoids an otherwise annual, biennial, or triennial bill of from $60 to $100 for medical care.

Another interesting example of the application of this principle is that of the Radcliffe Infirmary, a county hospital of Oxford, England. Under the plan in operation there, a family consisting of a man and his wife and children under 14 years of age, whose family income does not exceed $1,265 a year, receives both in-patient and out-patient service for a payment of 4 d., or 9.2 cents a week. For children between 14 and 19 years of age, an additional payment of 1 d., or 2⅓ cents a week, is required.

The insurance principle, as exemplified in the work of Roanoke Rapids and in the work of the Radcliffe Infirmary and County Hospital, appears to be the only remedy, but a most effective one for providing adequate medical care for a very large percentage of the people. Only a beginning has been made in its application. It is worthy of more extensive adoption and, unquestionably, we shall see in the near future an extended application. The development of sickness insurance is likely to be, in its early stages, in small and isolated groups. It holds out a strong appeal to industrial groups such as that at Roanoke Rapids. Its availability to agricultural groups will probably follow a more extensive use of the principle used in the industrial centers. As its use becomes more extensive and its value more generally recognized, we may expect to see the large insurance companies embrace it as a part of their protective program.

REFERENCE

1. Moore, Harry H. *American Medicine and the People's Health*, pp. 229–230.

Cyanogen Products used in Fumigation

THE use of poisonous cyanogen products for fumigation has increased during the past few years. They are largely used in the fumigation of vessels arriving from foreign countries, since they are powerful agents for the destruction of rodents and insects which may be carriers of disease.

Unfortunately some fatal accidents have occurred, not only on land, but also on vessels undergoing fumigation. The U. S. Public Health Service now advises the addition to these poisonous gases of enough tear gas to serve as a warning agent. The adoption of this measure will go far toward preventing such accidents in the future as have occurred in the past.

Skin Irritants*

CONSTANTLY increasing attention is being given to dermatitis as an industrial hazard and a greater number of cases are being reported, attributed to an ever growing number of irritants. In England, W. J. O'Donovan says that the question of invalidity due to occupational diseases of the skin is so great and so important that it deserves the investigation of nothing less than a special commission. Beintker regrets that in Germany industrial eczemas are not included as occupational diseases in the sense of the ordinance regarding the extension of accident insurance to industrial diseases, as the worker is often seriously handicapped in his earning capacity thereby.

In England compensation for industrial dermatitis has been in effect since 1918, and the yearly reports of the Chief Inspector of Factories show the increasing importance attached to this subject by the Home Office.

In this country, Ohio has required the compensation of cases of occupational dermatitis since 1921, but most of our states do not as yet require even the reporting of industrial skin affections. Realizing the growing importance of this subject and the lack of generally distributed information thereon, the Industrial Hygiene Division of the U. S. Public Health Service is conducting research on occupational dermatitis, but has not yet published a report.

This report reviews the literature on the subject from 1925 to 1928 and endeavors to classify and correlate it. Several general discussions appearing in 1926 will be considered, but specific references to case reports will be given only from the later part of 1926 to 1928.

CLASSIFICATION

Otto Sachs classified occupational dermatoses as follows:

Occupational Stigmata, as pigmentation, bronzing, scar formations and callouses
Caloric effects
Involvement of sweat and sebaceous glands, endogenous or exogenous in origin
Occupational nail diseases, as from arsenic, indigo, etc., or as in laundresses
Trade Toxicodermata; acute in form
Trade Eczemas, localized, chronic and relapsing
Dyes
Electric burns, X-rays and radium
Infections
Carcinomatogenous action, as from tar products

* Report of the Committee, presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

R. Prosser White classifies skin irritants on their chemical or physical nature and mode of action, as follows:

1. Mechanical or Physical Agents
2. Detergents, as warm water, soaps, etc., and all substances which emulsify skin lipoids
3. Anhydrides and Desiccators. Hygroscopic agents suck up water and generate heat in forming acids
4. Hydrolizers, as phosphorus, phosgene, mustard, etc.
5. Keratin Solvents, as sulfides, alkalies, etc.
6. Protein Precipitants, as heavy metal salts, formaldehyde, tannic, picric and carbolic acids
7. Oxidizers, as chlorine, chrome, etc.
8. Reducers, as tar, salicylic acid, arsenious acid, and paraphenyldiamine, etc.
9. Agents liberating acids from salts or from toxic nitro derivatives, as T.N.T. dinitrophenol, etc.
10. Keratonic or Neoplastic Agents, as arsenic, wood distillates, coal distillates, etc.
11. Biotic Agents, as vegetable, animal or microbic parasites
12. Sensitizers-Anaphylactoid, chemical, as mustard gas, benzene, etc., or vegetable, as various plant oleoresins, etc.
13. Anaphylactic agents, as vegetable or animal proteins

Foerster says that Lane has proposed the term "Dermatitis Industrialis" to be followed by qualifying adjectives such as "venenata," "eczema," etc., and an occupational term. He makes a plea, as does Lane himself, for more accurate detailed records of cases of industrial skin lesions. He uses Oppenheim's 3 groups of cases of industrial dermatoses.

1. Toxicodermias, with sudden onset following minimal exposures, and with progression after exposure ceases
2. Circumscribed occupational dermatitis following prolonged action of irritants on normal skin and improving on removal of irritant exposure. (They may at times be due to temporary increase of hypersensitivity or to increase in the strength or activity of the irritant.)
3. Occupational Eczema, dermatitis occurring in a sensitized or allergic skin with tendency to persist, to progress and to show exacerbations

DIAGNOSIS

White emphasizes some of the diagnostic difficulties met with in the study of dermatitis occurring in workers and presumably due to occupation.

A primarily internally produced skin disease may be mistaken for its traumatic counterpart. Has the patient a congenitally normal skin? Is the agent blamed a true causative agent? Does the irritant produce sensitization?

Otto Sachs states that blondes and old persons are especially susceptible to skin inflammations and various writers emphasize the special sensitiveness of very dry or very moist skins.

O'Donovan states that the reaction to external irritants depends largely on the skin rather than the influences. He devotes an entire paper to the psychologic factor in dermatitis. He states that an acute dermatitis venenata may become chronic if there is any hereditary trouble, mentioning, among the factors making for chronicity, chronic

urticaria, cheiropompholyx, congenital ichthyosis and a neuropathic taint. He states that psychic injury, emotional stress, nerve strain, anxiety, even greed and laziness, may be the most potent factors in educing and continuing a cutaneous disorder. This theory must influence diagnosis, treatment, handling and reporting of cases that are concerned in workmen's compensation acts. He gives case histories to support this statement.

Among etiologic difficulties he lists ignorance of the real nature of the substances being used by the worker and the fact that names of occupations do not always indicate the character of the exposure. Workers are often exposed to a variety of potentially irritating substances, and personal susceptibilities vary greatly to specific irritants.

Rost states that all possible exposures should be considered, and idiosyncrasy, seborrhea, or the presence of interdigital fungus infection must be excluded before a diagnosis of occupational dermatitis is made. Due to general or constitutional conditions, an acute trade dermatitis may become a chronic eczema or a preëxisting eczema may be covered by a dermatitis venenata. A congenital tendency to eczema may only develop late in life.

Various writers state that predisposition is essential for the development of an occupational eczema. The individual may be truly idiosyncratic, reacting at once, or only after sensitization following long or frequent contact, or only to the most violent irritants or caustics.

The most complete summary of the diagnostic factors in the consideration of occupational dermatitis was found in mimeographed lecture notes given by Dr. J. H. Stokes to medical students at the University of Pennsylvania.

Occupational dermatitis is due to an occupational irritant contact on a predisposed background. It may come on for the first time months or years after the patient first began work with the irritating substances. The tendency is to exaggerate the occupational factor and overlook the background presented by the patient.

Seborrhea, overwork, ichthyosis and nervous stress, the involution factors of late middle life, and pyogenic infection, both focal and local, are the chief predisposing influences. The last factor may be present in one or more workers in a plant, and be responsible for apparently severe irritations by a material not found to be especially irritating to other groups in other plants. The same may be true of the epidermophyton infections of hands and genitalia which are the conditions most generally confused with occupational dermatitis. The test of an occupational factor is usually, but not invariably, involvement of ex-

posed parts, improvement or recovery upon withdrawal from work, change of residence or careful protection of the affected parts, with relapse when exposure is resumed. If recovery does not occur on the institution of comparatively simple measures combined with withdrawal from exposure, some complicating general factor may usually be assumed. Additional important considerations include excitation of dermatitis by minute amounts of the toxic substance, frequent pyogenic complications and signs of autoinoculability.

Again, Sachs states that trade toxicodermata or acute dermatitis, usually self-limited and healing on removal of exposure, may blend into localized chronic and relapsing trade eczemas, characterized by general specific predispositions and developing on continuation of exposures. Sensitivity is seen in intense irritation, spreading and difficult healing. There are 4 steps to development of this type: (1) A specific inherited sensitivity, (2) resistant skin with little or no immediate response to irritants, (3) development of slight inflammation and accustoming to the irritants, (4) increasing of irritant exposure beyond the limit of accustoming. The nature of the irritant, the duration of the exposure and the concentration of the irritant play important parts.

Lane, in discussing the importance of definite standards in industrial dermatology, states that the first essential in consideration of a case is a reliable detailed history. Under working history he asks for previous occupations, length of time with present firm and on present job, details of process, of substances handled and of cleansing methods at home and in the factory, recent changes in working process or in cleansing methods, other workers affected, and other work done by the patient.

He gives as the essentials for the diagnosis of occupational dermatitis: (1) Amelioration on freedom from contact with suspected substance, and repeated attacks on new exposures, (2) lesions consistent with a history of exposure to the suspected substance, (3) exposure to substances known frequently to produce skin changes, (4) location of lesions (hands most frequent), (5) lack of evidence of exposure to other irritants, and (6) typical lesions.

For purposes of classification he makes 4 groups:

1. Definitely industrial
2. Probably industrial; a less clear-cut relation, a less irritating agent or less characteristic lesions or examination only a long time after onset
3. Doubtfully or possibly industrial
4. Definitely non-industrial

Mori discusses idiosyncrasy and anaphylaxis in relation to industrial diseases.

1. Anaphylaxis differs from idiosyncrasy, although in the case of certain agents the distinction between the two is not so clearly drawn as the following would seem to indicate.

2. Anaphylaxis is due to a proteid or a colloid substance; has a definite period of incubation; shows Pirquet's phenomena; and may be transmitted passively. Idiosyncrasy may be due to crystalloids; has no period of incubation; does not show Pirquet's phenomena; and is not transmitted passively.

3. The persons affected are apt to be: field laborers, horticulturists, gardeners, florists, wood-workers, milkers, bakers, etc.; herdsmen, workers around animals, furriers, hatters, textile workers, dyers, workers in brushes, horsehair, etc.; workers in gold, chemists, pharmacists, etc.; varnishers.

4. The symptoms are found in the skin and mucous membranes, the respiratory and circulatory systems, the blood and the serum. The nervous mechanisms are also involved. Local reactions due to contact with the offending substance also occur. Skin disturbances may include gangrene. Menstruation may be affected.

5. The differential diagnosis can readily be made by the uniform character of the symptoms and their sudden onset; the appearance of the reaction when the skin is treated with the offending substance in alcoholic solution, its appearance when the patient comes into contact with the offending substance, and its transmissibility.

6. The author reports 3 cases, 2 of erythema of the face with intense conjunctival hyperemia due to dry hay, and 1 of dermatitis due to vegetable sources.

7. The disease may be regarded as occupational, and hence has medico-legal significance.

Perutz discusses the relation of idiosyncrasy to allergic skin diseases.

STATISTICAL DATA

As an indication of the importance of dermatitis as an occupational hazard, several reports given in the literature are of interest.

Parmenter and Dubreuilk report 532 dermatologic cases seen at the industrial clinic in the Massachusetts General Hospital, or 1 case in 9 of the total. One-third of these were diagnosed as dermatitis or eczema, 147 being recognized as of industrial origin. There were 21 cases of epidermophytosis. Of the 147 cases of industrial origin, 86 had been exposed to the irritant substance for less than 9 months.

E. Weil reports 144 cases of occupational eczema, 25 of which were due to crude oil, 20 to alkalies, 19 to salts, 18 to tar derivatives, 15 to acids, 14 to physical agents, 9 to varnishes or lacquers, 9 to other organic agents, 8 were anaphylactic reactions, 4 each due to metals, alkaloids and living excitants and 3 to metalloids. These total 152; so there must have been some cases attributed to more than one of the above agents.

The 1926 *Annual Report of the Chief Inspector of Factories for Great Britain* lists 55 cases of chrome irritations and 187 malignant ulcerations due to the distillation products of coal and petroleum, with 49 deaths. In 1924 there were reported 429 cases of industrial derma-

titis, 61 from baking, confectionery and biscuit making, 28 from creaming and icing in the biscuit industry, and 52 due to alkalies. Among painters in one plant, 21 per cent were affected by dermatitis attributed to American steam distilled turpentine.

The *Occupational Disease Reports of Ohio for 1925–1926*, obtained through Emery R. Hayhurst, M.D., show 932 such cases, 75 of them possibly attributable to paints or paint materials and the balance from rubber factories. A careful analysis of these cases shows 29.3 per cent traceable to steam distilled turpentine, 28.1 per cent possibly to other turpentine, 20 per cent to naphtha, gasoline, etc., 11.8 per cent to "Turpo," "Varnoline," lacquer thinners or dopes, 2.7 per cent to oil and 8 per cent to other irritants. In the first half of 1926–1927 there were 20 cases of possible paint dermatitis reported, 2 from steam distilled turpentine, 3 from gum spirits turpentine and 9 from other paint solvents or diluents.

Foerster, referring to the per cent of occupational dermatitis among all skin diseases, quotes the following figures: Fordyce 2 per cent, Lane 10 per cent, Knowles 16 per cent, Oppenheim and Hazen both 20 per cent and R. P. White 25 per cent.

TREATMENT

Little that is new has been reported as to treatment of industrial dermatitis, but emphasis is laid on complete removal of exposure to the irritant, treatment of the general condition, and on mild applications.

Rost gives an excellent outline of treatment of industrial dermatitis.

Saffores reports excellent results from the injection of autogenous serum in cases of chronic occupational eczema.

TRADE DERMATOSES

In analyzing the reports of specific skin irritations in industry, we have grouped them under various headings which will be discussed one at a time. They are listed in the bibliography under these headings but not all of the articles will be considered in the text.

Kavelerow and Kogan report changes in the skin and nails in female glaze pourers and designers in porcelain and fine pottery factories, in the first group apparently due to the mechanical irritation of the finely ground glaze, and in the second an acute turpentine dermatitis with fissures and ulcerations. The latter cleared up when the women were forbidden to wash the molds with turpentine.

Carey P. McCord in 1925 called attention to cases of dermatitis in painters, etc., due to steam distilled turpentine, similar to those previously referred to in the English report. He listed a large number of possible irritants which might be

found in this product and not in gum spirits turpentine, and surmised that the increased irritation of this product might be removed by careful fractionation. His work indicated the greater irritation of steam distilled turpentines over gum spirit or destructively distilled turpentines, but did not identify the irritating factor. As a result of his report the Industrial Conservancy Laboratories made an intensive study of the problem, but did not complete the work. The Smyth Laboratory has been working on this problem for the producers off and on for two years, and is almost ready to present a final report and publish results. The clinical features, pathogenesis and treatment of turpentine dermatitis are discussed at length by Perutz.

Arzt discusses the skin affections found in agrarian workers, laying particular stress on the occurrence of fungus infections of various types, especially trichophytic, microsporon and favus, also mentioning actinomycosis and swine erysipelas, verrucose tubercles, anthrax, skin parasites, irritation from chemical fertilizers and from thermic extremes. Also he discusses plant dermatosis such as rhus and ivy. He reports an outbreak of infectious granuloma in milk handlers in Switzerland proved to be a staphylococcus infection.

Jordan reports skin lesions in a large group of post and telegraph employes in Moscow. Of 697 employes examined, 326 had skin injuries, 157 ulcers, 16 eczema, 15 warts, and 8 fissures. Of 927 employes visiting the dispensary, 225 had eczema, mostly not occupational, but 37 eczemas were considered occupational, often due to the spreading of paste with the fingers.

The British Home Office in 1927 issued a Welfare Order applying to bake houses with a cautionary note as to the prevention and cure of bakers' itch, emphasizing the importance of thorough cleansing of the entire forearm after work.

Foa reports eczema in tomato peelers in Italy which he attributes to either citric or malic acid in the tomatoes.

Cleveland reports dermatitis venenata in the rubber tire industry due to hexa-nitrodiphenylamine. The Ohio reports indicate that there are a number of irritating substances used in this industry.

Stern in discussing bakers' eczema in Germany says that the flour is not responsible and that, strictly speaking, it is not an industrial eczema.

Starobinski reports a case of vesicular dermatitis in a bread baker due to an unidentified fungus.

Klebanov and Emden report excoriations on the fingers and erosions of the nails in workers in Russian tanneries due to combined mechanical and chemical action in the handling of wet skins and exposure to tan liquor.

Wasserman, *et al.*, report industrial dermatitis from a clinic for glue factory workers.

Klebanov, *et al.*, discuss skin diseases among workers and employes of a basic chemical industry. This paper also has not been reviewed, nor has one on printer's eczema from washing fluids by Seitz.

PHYSICAL IRRITANTS

But two papers specifically discussing physical factors responsible for skin irritation have been noted. That by Weill discusses a case of hyperpigmentation due to continued heat exposure in a rolling mill employe. He suggests a hypofunction of the suprarenals due to heat. Goff notes that skin moisture encourages the development of pyogenic infections.

FUNGI

Blaisdell discusses epidermophytosis as industrial disease. Its importance has already been noted several times in this report. He states that in Massachusetts fungus infections following a dermatitis venenata or eczema may be compensable. He divides the epidermophytoses into 3 groups:

1. Intertriginous—eczema marginata
2. Hyperkeratotic—thickenings of soles and palms
3. Vesicular—on hands and digits

The third group is most interesting to industrial physicians.

Pijper reports 14 cases of sporotrichosis among South African native miners due to Rhinoclaudium Beurmanni, the pathogenesis of which was confirmed by animal experiments.

PLANT PRODUCTS

Among plant products, other than turpentine, already discussed, cashew nuts, Chinese lacquer, teakwood, linseed oil, flax, macassar wood, and tobacco leaves have been incriminated in various papers, and Touton offers a general discussion of dermatitis caused by plants and plant products. He makes 3 groups of subjects: those generally sensitive due to idiosyncrasy, those becoming sensitized by frequent handling, and those remaining immune. In addition to phytogenic dermatitis he discusses cases of pseudophytogenic dermatitis really due to plant parasites, as fungi or animal parasites.

Vokoun finds linseed oil dermatitis, particularly from the handling of South American seed, and suspects foreign seeds as the cause.

D'Agostino traced the flax workers' dermatitis to wild camomile in the fields.

ANIMAL IRRITANTS

Two papers discuss animal irritants. Klauder, *et al.*, report a severe erysipeloid among commercial fishermen along the northern New Jersey coast due to infection with swine erysipelas bacilli, and Vedrov gives data on industrial dermatosis of cocoon winders.

INORGANIC IRRITANTS

Among inorganic irritants, chrome, sulphuric acid, nickel, rock salt, alkali and chlorine are mentioned.

Forster discusses protection of workers in chromium plating establishments in the *International Labor Office Studies*, and Blair reports 12 cases of chrome ulcers in chrome plating plants. He uses 5 per cent sodium hyposulphite to neutralize the acid on the hands.

Schwartz reports skin erosion and irritation of the air passages in men cleaning boilers that had been fired with a petroleum by-product, the sulphur content of which oxidizes to sulphuric acid during firing and settles in the flues.

In discussing so-called nickel rash, Kolzoff reports on the examination of workers in galvanoplastic nickel workrooms in Leningrad. He states that nickel only acts on skin dried by exposure in preparing the metal for nickeling.

Cabot reports an interesting case of recurrent subacute occupational dermatitis due to caustic originally, but at times aggravated or made to recur by heat and by mechanical irritation.

Thurber reports furunculosis in handlers of rock salt in ice cream factories, the salt irritation being responsible for the chronicity.

Telcky reports acne from chlorine in industrial plants.

ORGANIC IRRITANTS

Among organic irritants not previously mentioned we find references to oil, creosote, tar products, para-yellow, aniline pencils and calcium cyanide.

Freund reports a case of melanoderma toxica lichenoides et bullosa in an Italian worker exposed for several months to the fumes of melting tar. He had previously reported a similar case.

Three writers report melanosis or Riehl's disease in workers in mineral oil. Sezary, *et al.*, report follicular hyperkeratosis, oil papules and melanosis in a metal lathe worker. Ravaut, *et al.*, report follicular keratosis and melanosis in a polisher in a piano factory using machine oil, and Chentov discusses professional tatooing in workers in oil mills.

Hudelo also reports a melanosis in a railroad grade worker handling creosoted ties, and suggests the possibility that the creosote contains substances which enter the blood and are photodynamic.

Ravaut also reports a case of oil acne and keratosis becoming cancerous in a worker in an automobile factory handling gasoline and oil. The lesions began 2 months after starting work.

Tarneaud reports occupational sebaceous folliculitis of the nose among greasers of metal parts, one working under a continuous jet of oil.

In *Archives of Dermatology and Syphilis,* a case is reported for diagnosis of a dermatitis of the forearm starting as an erythematous papule and becoming macular and exfoliative, resembling seborrheic dermatitis. There were also lesions in the fauces and large auxiliary lymph nodes. The subject was an oil station employe.

Magee, in the *Journal of the American Medical Association,* reports dermatitis due to para-yellow, probably para-nitro aniline, and Casozza reports erythema, urticaria, eczematoid and bullous dermatitis with general symptoms from calcium cyanide used as a powder in agriculture in Italy.

Iselin reports cases of necrosis of the hand from injuries with anilin pencils.

Oliver reports 15 cases of dermatitis in rotogravure workers attributed to para-nitranilin-red, or a derivative thereof, used as coloring matter in ink.

CARCINOGENIC SUBSTANCES

A consideration of skin irritants must include not only such substances as produce acute or sub-acute inflammatory reactions but also keratogenic agents, and others that act slowly, eventually producing precancerous and cancerous conditions.

The subject of trade cancers is well handled in a paper by R. Prosser White. He states that specificity must be present in an agent before it can initiate a cancer. Such agents are generally keratogenic. Acute cancer developing before the healing of a trauma is rare and probably incidental. There are but few cases recorded of cancer following burns or scalds, and only limited lists available of latent cancer developing at the site of an old scar. Cancers formerly attributed to radiant heat are now thought to be due to the action of ultra-violet rays. Arsenic is the only inorganic substance against which there is conclusive evidence. Distillation products of vegetable matter, whether coal or tobacco, appear to possess carcinogenic properties. A biologic precancerous stage precedes a local cancer. Apart from the agent there must be a cancerous state, liability, constitution or disposition, either general or cellular.

Roussy and Heraux give an extended resumé of the occupational cancer problem, discussing cancer development in eight industrial groups.

Chimney sweeps' cancer seems more prevalent in England than elsewhere and

is attributed to soot formed from improper combustion. The scrotum is the usual primary seat due to the thin epidermis and numerous sebaceous glands. The testicles and penis are involved secondarily by the development of benign papillomatous cutaneous lesions. These cases are similar in origin to cancer cases reported in women working in coal, to that of a gardener using soot and developing cancer on the back of his hand, and eyelid cancers among coal carriers.

English statistics are quoted showing in 1880–1882, 242 chimney sweeps with 49 developing cancer (202 per 1,000); in 1884–1890, 156 deaths per 1,000 of chimney sweeps from cancer; in 1900–1902, 133 deaths per 1,000 from this condition—a gradual decrease.

A paper by Bang covers the same ground.

Roussy considers cancer of tar and pitch workers. Workers with oily tar are apt to develop scrotal cancer while pitch workers are affected on the facial areas, more seldom on the limbs and trunk. The tumors are usually epitheliomata of spinocellular type and occur after long exposure to tar. Workers in paraffine may develop skin cancer after long exposures (25 to 30 years), usually first as squamous papillomata, later ulcerating and in some cases becoming malignant. Leitch is quoted as having produced paraffine cancer experimentally in mice. Textile workers' cancer, reported most frequently as scrotal cancer of mule-spinners, has been quite frequent in England, but rare in America. Until recently it was attributed to oil spraying on the workers' overalls and to pressure on the parts aided by heat during work. Leitch has produced cancer in 30 out of 75 mice treated with oils, the heavy, less refined oils used for greasing and lubricating being active. Cancer is at times met with in petroleum refiners, but not so frequently as in the above mentioned groups. Of 260 scrotal cancers in England from 1913 to 1923, the majority were in chimney sweeps, textile workers, tar workers and oil workers. The last group considered are cancers due to X-rays or radium, also occupational cancers but not usually industrial.

In addition to these general discussions various case reports and discussions of cancer in specific groups have appeared.

Bordier discusses radiologists' cancer.

Stoel claims good results from the use of radium on experimental tar cancer in animals, stating that the rays kill cancer cells sooner than non-cancerous.

Bordier has cured Roentgen ray cancer by diathermocoagulation.

Sherber reports the case of a man, 55 years old, employed in moistening animal hair with spindle oil who developed on his hands, forearms, and a little on the face, an efflorescence, irregular intense reddening, epidermal thickening and scaling, with later formation of horny epithelium, the formation of a kroner sized tumor, centrally ulcerated, on the right thumb metacarpal; rapid ulceration, glandular swelling and active connective tissue inflammation. The tumor proved to be a squamous epithelioma. He states that Bloch and Widmer obtained by vacuum distillation at 230° C. a high molecular cyclic hydrocarbon that was carcinogenic. He feels that there is no one specific carcinogenic substance but that various irritants may so act on predisposed tissue.

O'Donovan reports the development of multiple skin cancers in a gunsmith who had cleaned guns for 39 years with Rangoon and other paraffine oils, his clothing being usually oil soaked. Fifteen horny celled squamous epitheliomata were removed.

Spitzer reports multiple primary paraffine carcinomata in a 44-year-old worker in a mineral oil refinery, extracting paraffine from crude oil residue, and coming in

contact with soft oil cakes. His face and hands were oil spattered and his clothing saturated. He believes that empyreumatic materials in crude oil are the chief causes of paraffine itch and paraffine cancer. No skin diseases are traceable to handling pure paraffine in candle factories.

Lazzarini reports 6 cases of skin cancer among coal workers, 1 case in a coal-tar worker in Dr. Truffi's clinic and 1 case of precancerous dermatosis in Dr. Piccardi's services. He reports in detail 2 cases of his own. He differentiates coal-tar cancer from that due to paraffine and other coal products. He says coal-tar cancers have a relatively less grave prognosis and less tendency to metastasis. He discusses the development of the precancerous state and its treatment.

Four papers consider mule-spinners' cancer. Wilson, Southam, and Savatard blame the mineral oil, Savatard claiming that ichthyosis simplex is a fertile soil for cancer, keratosis being secondary to ichthyosis.

Robertson claims to show that oil plays little if any part in the etiology of mule-spinners' cancer. He lists the etiologic factors as dirty scrotum, dyes, friction from rough in-seam of overalls worn next to the skin in hot spinning rooms and the use of inelastic braces.

Kingsbury reports scrotal cancer in a man employed in anti-malarial oiling using high boiling fractions of oil. He states that carcinogenic substances have been found by Leitch in the high boiling fractions of coal-tar, Scottish shale oil and oil from Borneo, Assam, Egypt, Burma and Badapur.

No papers dealing only with experimental cancer production have been included in this review.

CONCLUSION

We would emphasize the great importance of industrial dermatitis to the industrial physician, the necessity of detailed study of cases and consideration of all possible irritants to which the worker is exposed; of noting extent and duration of exposures, considering the personal and group factors influencing susceptibility, and not overlooking the importance of the epidermophytons and of pyogenic infections as contributing causes or reasons for slow healing.

Few substances used in industry act as irritants to all skins and few will not irritate especially susceptible skins, whether susceptibility be due to idiosyncrasy, sensitization or constitutional disease.

In general, protection of exposed skin, thorough cleansing after exposures and the use before work of protective substances such as petrolatum, lanolin or vegetable gum pastes and of similar substances after cleaning on skins deprived of natural protecting oils will prevent many cases of skin irritation. While there are few if any specific carcinogenic substances, a variety of organic oily substances will so act on predisposed skins.

HENRY FIELD SMYTH, M.D., *Chairman*

NOTE: The extensive bibliography which accompanied this paper is not printed because of lack of space. Copies of this can be obtained from the Chairman, Henry Field Smyth, M.D., University of Pennsylvania, Philadelphia, Pa., or Carey P. McCord, M.D., Section Secretary, 34 West Seventh Street, Cincinnati, O.

Work of Committee on Administrative Practice*

THE most outstanding concrete result of the seven years' work of the Committee on Administrative Practice has perhaps been the *Appraisal Form for City Health Work,* issued in 1925, and revised after experimental use for one year. The revised form was printed in January, 1926, and at that time it was announced that the form would again be recast after three years. Your committee now presents to you the first triennial revision of this document.

It will be remembered that the *Appraisal Form* was originally prepared with considerable trepidation, and, on the whole, the favor which has attended it, and the stimulation of health practice which has followed on its use, have been exceedingly gratifying to all concerned. The check sheet[1] prepared by H. S. Mustard, M.D., Health Officer, Rutherford County, Tenn., is one of the most recent evidences of its value. However, as we pointed out last year:

> The committee has felt that there were two very real dangers in the practical application of the appraisal principle. It might, on the one hand, invite unjustified and damaging criticism of departments having low scores; and it might, on the other, lead to undue standardization and to stagnation on the part of cities having high scores. The first of these hazards has, so far as we are aware, been completely avoided by the use of the *Appraisal Form* in an individual city only with the approval and on the request of the health officer and by the avoidance of any comparison of total scores obtained by various cities on a comparative basis. The second hazard we have planned to obviate by revision of the *Appraisal Form* at 3-year intervals, and the first revision will be completed during the coming year and presented at the 1928 Annual Meeting. It is planned, not only to alter items in the present form which have been shown to be theoretically and practically unsound, and to increase levels of attainment required for a perfect score to keep pace with current progress; but also, if possible, to include certain new items not now included at all.

The hopes thus expressed a year ago have been fully realized through the devoted labors of a sub-committee headed by George T. Palmer, D.P.H., and the *Appraisal Form* as now revised differs from the old in three general ways:

1. Individual items have at many points been modified, either to eliminate elements of measurement which have proved to be unfair, or to raise or lower quanti-

---

* Report of the Committee, presented to the Health Officers Section of the American Public Health Association, at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

tative standards in accordance with experience and with the progress of the development of municipal health services. In particular, the sections on school hygiene and on popular health instruction have been radically recast. It is believed that, from this standpoint of adjustment in detail to the accurate evaluation of health practice, the new form is vastly superior to the old one.

2. It has been found possible to include at this time two of the newer lines of health activity which promise to be of predominant importance in the future—the control of cancer and the control of heart disease. We realize that the schedules for these activities are in many respects tentative and have therefore given to them only very small weight in comparison with the more familiar activities. We do feel, however, that it is most important to recognize the real problems of the future, in which the progressive health officer must interest himself in an increasing degree, and at least to direct attention to the need for an accurate knowledge by the health officer of what is being done in his community with respect to these problems.

3. A change of fundamental importance has been made in the general plan of weighting activities. The original form included 8 major types of activity, ranging in value from popular health instruction with 20 points, to communicable disease control with 175, the total of all points scored in the *Appraisal Form* being 1,000. In practice it has been found that comparison of total scores on a basis of 1,000 was of little practical value and often misleading, and that in the actual use of the form it was very common for health officers to re-compute the score for each activity on a basis of 100 per cent, to obtain a more direct measure of the activity in question. We believe that it is more important for the health officer to know how each of his activities compares with other activities in his own city and with similar activities in other cities, than it is to know how his total score compares with the total score of some neighboring community. In the new form, therefore, each activity is scored on a basis of 100, and a total score on the basis of 1,000 can be obtained by applying a series of activity weights. Both activity scores and total score can be obtained in either case, but according to the present plan the activity scores come out directly and the total score if desired must be computed afterward.

We suspect that there may be members of the Association who will find these changes unduly radical, but we have been influenced by the belief that it is first of all essential to keep the *Appraisal Form* a fluent instrument for measuring current progress, and we believe that the changes which have been made will tend toward the objective of the entire work of the committee—the stimulation of sound and progressive improvement in the health service of the country.

In addition to the revised *Appraisal Form,* the committee presents three sub-committee reports which are indicative of the whole-hearted devotion which all the members of the committee have rendered during the year. C. Hampson Jones, M.D., has a progress report on standard health department reports; Henry F. Vaughan, D.P.H., a report on model health department ordinances; and George C. Ruhland, M.D., a series of model record forms[2] dealing with other fields of activity than those covered last year.

The Sub-Committee on Organized Care of the Sick, headed by

Michael M. Davis, Ph.D., has prepared during the year a statement of policy regarding surveys of hospitals, clinics, city physicians and similar facilities. The statement after having had the benefit of the criticism of health officers through distribution via the *Health Officers' News Letter,* was printed in the JOURNAL.[3] This statement was also distributed to some 300 community chests, welfare federations and councils of social agencies in the United States and Canada. Surveys within the proper scope of the committee will be regarded for the present as including such matters as the need for hospital beds, clinics or other organized curative facilities of a community; the social and economic groups for which such facilities are needed; the geographical distribution and the interrelations of these facilities to one another and to other interests and agencies of the locality. Surveys of this type would ordinarily be conducted in connection with a study and appraisal of the official health department, the health work of the board of education and voluntary agencies (Visiting Nurse Association, tuberculosis association, etc.), requested by the health officer.

Hitherto, with the exception of the preparation of a tentative *Appraisal Form for Rural Health Work,*[4] the activities of the committee have been limited to municipal health practice. During the past year, however, thanks to the generosity of the Commonwealth Fund, it has been possible to undertake, at the request of the state health officers concerned, state health department surveys in Massachusetts, Michigan and Ohio. The Commonwealth Fund has also contributed a special fund for the initiation of a study which we have long had in mind. It is planned during the next two years to survey approximately 50 rural counties in different parts of the United States, with the counsel of a committee of the Surgeon General's Conference of State and Territorial Health Officers. This work began most auspiciously last summer, and we are fortunate in being able to carry it out in coöperation with the recently organized Committee on the Cost of Medical Care, whose field agent will obtain in some of the same counties visited by us data as to the facilities for the care of illness which are so closely interrelated with the official and voluntary health agencies of the community. It is believed that this study when completed will give us a sound basis for the working out of model health programs adapted to rural areas of different sorts and for the revision of the *Appraisal Form for Rural Health Work* along sound and constructive lines.

In addition to the general studies of the committee, we have as usual conducted on request a number of local health surveys besides the state studies in Massachusetts, Michigan and Ohio, to which reference has been made. The communities covered since the last An-

nual Meeting include: Cattaraugus County, N. Y., Clarke County, Ga., Fargo, N. D., Monmouth County, N. J., Montreal, Can., Rutherford County, Tenn., St. Louis, Mo., Spartanburg, S. C., Syracuse, N. Y., Warwick, R. I., Tompkins County, N. Y., Marion County, Ore., and Los Angeles County, Calif.

The committee has continued its active coöperation with the General Federation of Women's Clubs which, with our aid and that of the Metropolitan Life Insurance Company and the American Child Health Association, has been conducting with increased success a competition in the filling out of a schedule of local community health activities. The schedule filled out by members of the Federation was returned this year by 100 cities and 45 counties, and the state having the best record for such activities and receiving the prize in the form of survey service offered by your committee and by the American Child Health Association this year was North Carolina.

Coöperation with the Chamber of Commerce of the United States has also been continued and seven special bulletins have been prepared by the committee staff for dissemination by the Chamber. A plan for a life conservation contest under the auspices of the Chamber, to be conducted with the coöperation of the committee, is now under consideration.

The personnel of the committee has remained unchanged with the exception that Francis G. Curtis, M.D., and James Roberts, M.D. (ex officio members from the Health Officers Section), have been replaced by E. L. Bishop, M.D., and A. J. Chesley, M.D. The fact that Dr. Bishop became an ex officio member created a vacancy in the appointive membership and this vacancy was filled through the appointment of Charles V. Chapin, M.D.

The committee has for several years felt very keenly the need of a member from the Public Health Nursing Section to aid it in dealing with the nursing problems which form so important a part of its surveys and appraisals. In order to fill this need for the time being the committee has invited Sophie C. Nelson, R.N., to serve as a special adviser to the committee on such problems, and is deeply appreciative of the service she has agreed to render in this connection.

The activities of the committee have been made possible during the past year by a continuance of support from the Metropolitan Life Insurance Company which has given $7,500 and from the Milbank Memorial Fund which has given $5,000 to the Association for its work. In addition to these old friends, the John Hancock Life Insurance Company has made a grant of $5,000 to aid in the work of revising the *Appraisal Form* and in the work of the Sub-Committee on Model

Health Ordinances and on the Organized Care of the Sick. The Commonwealth Fund has given $5,000 for the state surveys and $12,500 for the rural surveys. In spite of this generous aid the resources of the committee have not been fully adequate to the tasks imposed upon it, and an unreasonable burden has been placed upon the staff. It was recognized of course that special studies like the state survey and the rural health survey must be supported by special grants, but it is also essential to remember that the committee needs between $25,000 and $30,000 for general overhead expenses. Every effort has been made to make the local surveys—conducted for the benefit of the communities concerned rather than for the collection of fundamental data—self-supporting, but this is difficult if not impossible to do in every case. In view, however, of the demand for aid from health workers in all parts of the country and of the use to which they are putting the information obtained by the committee, we feel that resources will be forthcoming for the future.

Maternity Insurance in Italy

IN Italy, the only country in the world where compulsory maternity insurance was made the subject of a special law, the number of insured women increased from 640,000 in 1922 to nearly 900,000 in 1927. These women and their employers pay contributions in equal amount into a fund out of which benefits are paid at the time of confinement or miscarriage. To these benefits certain amounts are added from the national treasury. The number of women who received such benefits rose from nearly 34,000 in 1922 to over 40,000 in 1927 and the amounts paid from over three million lire to over four million.—*Boll. d. Lavoro e d. Previdenza Sociale*, Rome, 50, 3: 404 (Sept. 30), 1928.

How to Use Civic Clubs Effectively in Promoting Health Programs*

E. L. BISHOP, M. D., FELLOW A. P. H. A.

Commissioner of Health, State of Tennessee, Nashville, Tenn.

IN THIS country, private effort is a social force ready to the support of any social movement for legitimate enterprise. Particularly in recent years, this private effort is finding expression in the organization of groups with some common interest or for the purpose of promoting civic progress in one or more of its phases. It is in this broad sense that the term "civic groups" is used for the purposes of the present discussion. Hence it includes such groups as chambers of commerce, luncheon clubs, parent-teacher organizations, and many women's clubs, even though the latter, in many instances, may be organized for cultural study rather than civic enterprise.

There can be no more important civic service, whether for the community, state or nation, than protection and promotion of the public health, since disease and physical deficiency directly influence man's ability to work and create wealth for the promotion of his social welfare. Society has recognized this fundamental fact by the erection of machinery for the promotion of the public health in each element of government of this country with the delegation of appropriate powers and responsibilities in the discharge of health functions. In addition, many private and voluntary organizations have been established through philanthropy or public effort. These organizations act as constant stimuli and supports to the health agencies of government.

If we grant that civic groups are organized for the promotion of civic enterprise and if protection and promotion of the public health be an important and legitimate civic enterprise, the community of interest is obvious and it is possible to use civic groups effectively in the promotion of health programs.

Necessarily, the health agency, whether central or local, must exert the leadership essential to the development of coöperation and support from the civic groups. The question confronting us is: "How

* Read at the Second General Session of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

may this leadership be properly exercised?" Surely the first need is that the executive or health officer shall have subjected his health problems to critical analysis and determined upon the machinery, organization and methods essential to solution. As a part of the analysis, death rates and other indices of the community health problems will have been studied carefully, not only in their local relationships but also in relation to communities having more nearly adequate health organizations. The health executive is then in a position to carry his message and plea for coöperation to the civic clubs.

Since securing the essential machinery for solution of his health problems involves the question of financial support, a sound appeal can be made to business organizations. The economic disadvantages presented by high death rates from communicable infections, the high cost of physical inefficiency of labor, and the bar to industrial expansion offered by excess mortality rates, can be presented as sound arguments to chambers of commerce. Industry today is inquiring into the health conditions of areas in which it seeks expansion. To the luncheon clubs, the health executive may carry essentially the same general message presented to chambers of commerce, for they too consist principally of business executives. To parent-teacher organizations, he may present not only the general health problems, but may emphasize particularly the child health problem and school health conditions. Throughout each presentation, he must make the point that the campaign for good health is not an isolated engagement, but a continuous warfare. This is perhaps the most important essential of all in view of the fact that the health organization must develop the sustained interest and support of civic clubs if such groups are to be effectively utilized as a social force.

Proof of the effectiveness of this method of approach is found in the success attending the efforts of the State Conference of Chambers of Commerce and Civic Clubs in Tennessee relative to securing expansion, not only of the program of the State Health Department, but also of local health departments. This conference meets in annual assembly with delegates from constituent chambers of commerce, luncheon clubs and other civic organizations. In 1924, the health committee of a chamber of commerce became deeply interested in the fact that Tennessee was being inadequately served by its health organization, due to the complete inadequacy of existing facilities and machinery for health protection. An appeal was made to the State Health Department for information, and an entire afternoon of the program of the state conference was devoted to the presentation of very carefully and exactly compiled information relative to the state's health problems and the facilities essential to their solution.

It is important to emphasize that this health committee of a chamber of commerce, composed as it was of both business men and practicing physicians, had complete charge of the program and was served by the State Department of Health rather than itself serving the department.

In the development of the program, the committee called upon leading physicians of the State Medical Association, leading business men of the community and the State Department of Health for the presentation of information essential to consideration of the state's health problems by the conference. The State Health Department was required to present the comparative studies of mortality rates, physical deficiency rates, per capita appropriations for the country as a whole, a specific budget that would provide for such growth in a single biennium as was consistent with good business administration and a comparison of local health organization with similar developments in other states.

Throughout the preparation of these data, the State Department exercised the most scrupulous care as to accuracy and called upon the U. S. Public Health Service for a survey of its facilities and recommendations for expansions in order that it might have the benefit of a broad, detached point of view. From the data so compiled, the committee and its speakers developed their presentations, and so effective were these that during the entire program not one word of objection to substantially increased appropriations and to substantial expansion of activity was voiced by a single delegate or attendant at the conference. Not only was this true, but the conference instructed its Resolution Committee to prepare strong resolutions voicing the approval of the conference and bespeaking the coöperation of all business organizations in the translation of the recommendations into action by appropriating bodies. The resolutions were unanimously adopted, and each delegate was instructed to carry the program to his home organization and thoroughly familiarize the local community with the objectives of the chambers of commerce. Speakers were delegated from local chambers of commerce to appear before local medical societies and present the program for consideration. Thus business was seeking the coöperation of medicine, which was given to the fullest extent.

Practically every medical society in the state passed resolutions petitioning the State Legislature to increase substantially the appropriation for health work in the state. In addition, the local medical societies delegated speakers to attend the community meetings with representatives from the local chambers of commerce in an

effort to carry the message to the general public. This measure was extremely effective and the net result of the activity by the chambers of commerce and the medical societies was the adoption of a 60 per cent increase in the budget for the State Department of Health, with practically no dissenting opinions in the State Legislature.

When it is considered that this entire project was organized and carried out by business executives and busy practitioners of medicine who paid their own travelling expenses in all instances and who received nothing whatever in recompense save the satisfaction of a service performed, the accomplishment must stand forth as a most remarkable achievement by a group of civic organizations.

The state conference has not, however, been content with its primary accomplishment. Throughout the four years since its first activity in behalf of health work, it has sustained its interest, and each year has called upon the State Health Department for a report of progress. Each biennium it has developed plans for further expansion of health work in coöperation with and in support of the State Department of Health. Individual chambers of commerce have supported the expansion of local health work, and throughout the state business is constantly and increasingly expressing its interest in the development of better health organization.

The specific results of this plan of action have been an increase in the per capita appropriation for the State Health Department from 3.3 cents in the biennium 1923–25, to 5.24 cents in the biennium 1925–27, and 10.27 cents in the biennium 1927–29. Thus, the state is now appropriating and spending more than three times the sum for health protection that was being spent when the civic groups first began direct support of the health program. In addition, municipal appropriations for the protection of public health have grown and the percentage of the rural population under the protection of full-time county health work has increased from 13.5 per cent in 1923, to 37.9 per cent in 1928.* Increased appropriations and advances in public health organization are principally attributable to the coöperation of civic groups.

It is easily deduced from the foregoing description of our experience that civic groups may be effectively used in two relationships to health programs. First, in securing essential funds from appropriating bodies for expansion of the health machinery such groups can render a most necessary service. Second, civic groups supply that link in the community organization which will enable the health machinery to decentralize its efforts in such a manner as to serve the community more effectively. There is an additional avenue of serv-

* 1926 population estimate used for 1928 percentage.

ice in the latter relationship for parent-teacher organizations, and local women's clubs are especially helpful in local health work.

An example of most effective use in such relationship recently came under the writer's observation. The County Health Officer of Davidson County wished to secure the administration of diphtheria toxin-antitoxin to a large group of preschool children. It was clearly impossible for his organization to reach each individual family and secure the coöperation of the parents in bringing the younger age groups to a clinic. He, therefore, requested the school teachers to place the matter before the local parent-teacher associations with the request that they assume this responsibility. In turn, the parent-teacher associations organized each community into blocks and visited the individual homes in an effort to secure the necessary attendance of preschool age children on a specific date at the local school. So effective was this organization that, in one small school community, more than 150 children between the ages of 6 months and 5 years were given toxin-antitoxin, and similar results were obtained in other schools.

Often, the complaint is made that there are no existing civic groups through which to work. If this be true, it is usually because effective leadership has not been exerted in the development of civic groups. Such a condition existed in Rutherford County, Tenn., when the Child Health Demonstration was first established in 1924. The director of this demonstration was not discouraged, however, and proceeded with the development of "community health committees," the chairmen of which constituted a part of the membership of a central county health committee. The remaining membership was made up of members at large, including representation from the medical profession, the dental profession and the educational system. In the evolution of this community organization certain of the community health committees are becoming parent-teacher associations, which in turn appoint subcommittees to act as the community health committee. This is an entirely satisfactory and desirable development, since it expands the community organization and promotes the exercise of local initiative.

Experience in Tennessee forces us to the conclusion that civic clubs may be effectively used in promoting the health programs of the state and local health organizations. It further demonstrates that such groups are useful not only in securing increased appropriations for the expansion of health machinery, but also in increasing the efficiency and spread of activity by existing local health departments. There is also evidence that, if existing inadequate civic groups are properly utilized, the health program may supply that community of interest which will make possible the development of more effective community organization.

Registration Affairs*

ONLY 4 states remain outside the U. S. Registration Area—Nevada, New Mexico, South Dakota and Texas.

Now that the goal of completing the registration area before 1930 is in sight, it is high time to consider some of the remedies needed to improve not only the percentage of registration throughout the country but also the quality of that registration.

A better death certificate is needed and the suggested form for the next decade will be discussed by the Committee on Forms and Methods of Statistical Practice.

To improve attempts to analyze mortality and birth data by occupations, more careful statements of occupations are needed upon birth and death certificates. The new birth and death blanks have been so drawn up that better statements of occupations should be forthcoming.

To permit greater refinement of the crude birth and death rates, more attention should be given to correct these rates for the births and deaths of non-residents.

These annual meetings of the Vital Statistics Section should from now on serve more than ever before as the clearing house for state and city registrars to exchange ideas so that every registrar will learn about every successful registration method and device employed elsewhere.

In some states, the situation can doubtless be improved by slight amendments to the present laws. In other states, greater publicity regarding the benefits of good registration might lead to bigger state appropriations for the work and so to marked improvement in registration itself.

The following are a few of the registration matters which need further careful consideration:

1. Should $.25 for each certificate be held as the reasonable remuneration for a local registrar, or should it be increased to $.50, or should this be done in some other manner?

Mr. Fales has suggested as a possible method that the increase be made by paying each registrar a base rate of $2.00 each month providing that the report is mailed to the state registrar promptly, in addition to the present fee of $.25 for each certificate filed. Mr. Fales continues:

---

* Report of the Committee, presented to the Vital Statistics Section of the American Public Health Association, at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

This is the basis of pay in New York State, which I believe largely contributes to their practically 100 per cent reporting of registrars each month.

The advantage of this method of increase is that the registrar in a sparsely populated district who now may receive only $5 or $10 for his year's service would receive a relatively much greater increase than a registrar in a town now receiving $100 or more for his services. I think you can readily see the advantage of such a method of increase in helping us secure better pay for registrars in strictly rural districts where the amount of work necessary to secure a certificate for an unreported birth or death is considerably more than it is for a registrar of a city or town, and it is in our sparsely populated districts that we must make it worth while for registrars to go out and get up certificates.

2. Should physicians and undertakers be tabooed as local registrars?

3. Where there is a full-time county health officer, should he upon his request be appointed an agent of the state registrar so that the certificates of births and deaths could be routed through this health officer on condition that they be passed on promptly to the state registrar?

We cannot emphasize too many times or too strongly our sincere conviction of the great benefit which results from the frank exchange of ideas at these meetings of the American Public Health Association, not only in the general and section meetings but in the frank discussions which almost inevitably follow the meeting of any two registrars in the lobbies, in the dining halls, and on the sight-seeing tours. Frank discussion of all registration problems is in order at all times at these annual meetings.

Mexican National Committee on Infant Welfare

A NATIONAL committee on infant welfare (Comite Nacional de Proteccion a la Infancia) has been established in Mexico City for the purpose of combating infant mortality. It is a private organization, but it has announced its intention to coöperate with the Government.

A few days after its organization the committee started a campaign for raising 1,000,000 pesos, to which the Federal Department of Public Health responded with a contribution of 256,000 pesos.—*El Universal,* Mexico City, Jan. 25, Feb. 3 & 5, 1929.

When Are Meats or Fish Spoiled?*

IT is extremely difficult to tell with accuracy when food is spoiled or decomposed. There are all degrees of spoilage ranging from practically normal to a condition of putrescence. Aside from the ordinary organoleptic tests such as appearance, odor and taste, few really satisfactory criteria or tests for spoilage are known. We are not concerned primarily with the far advanced cases of decomposition, which are readily perceptible to the senses, but with those incipient, doubtful, border-line cases which we encounter every day not only in food inspection work but in our own homes as well. A decision must be made. Is the meat fit to eat? Are the oysters sound? Is this fresh fish?

Meats, fish and shellfish possess a very important place in the diet of man. In 1927 the consumption of meat per capita in the United States was 140 pounds; of fish and shellfish about 18 pounds. The high quality and wholesomeness of these foods should be guaranteed to the consuming public. Meats and fish are particularly favorable pabula for the rapid growth of bacteria and the production of toxins. Certain decomposition products such as ammonia, hydrogen sulfide, indol, amino acids, trimethylamine, free fatty acids, etc., are known to be formed in certain types of meat and fish spoilage. Are there not perhaps simple tests by which the laboratory worker or even the inspector may verify his organoleptic observations? Likewise is it not possible that simple direct microscopic or bacteriological technics may be perfected which will aid greatly in detecting with speed and precision incipient spoilage in these foods?

Your committee, sensing the attitude of the public, considers that this question of the detection of incipient decomposition in meats, fish and shellfish should be brought to the attention of our Section. In order to bring the subject up to date, a survey of some of the more important contributions to the literature of meat and fish spoilage with particular reference to methods of detection has been made.

Weinzirl[1] has given an excellent description of the spoilage process in biological terms:

But spoilage is a complex process. In the first place it is a souring of the meat, due to fermentation of the carbohydrates present, by aerobic, facultative and an-

* Report of the Committee on Meat, Fish and Shellfish, presented to the Food, Drugs and Nutrition Section of the American Public Health Association, at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

aerobic bacteria; secondly, it is a digestion of the proteins by aerobes and facultative anaerobes without abundant evolution of sulfides; thirdly, it is the production of indol, skatol and other vile smelling compounds by aerobic, facultative and anaerobic bacteria; and fourthly, it is putrefaction with the production of sulfides by anaerobes.

It is well known that spoilage may be due to the cell enzymes alone—such as autolysis. Fellers and Parks,[2] Hunter[3] and Almy[4] have reported independently on certain types of spoilage in crabs, salmon and sardines which are autolytic rather than bacterial in nature. On the other hand, where microörganisms are present, the spoilage process is still due to extracellular enzymes elaborated by them. As stated by Effront:[5]

> It is impossible to give a simple and unchangeable scheme for decomposition, since the quality and the quantity of the products formed are dependent upon the nature of the acting enzymes, which, themselves, are functions of the species of bacteria present, of the albuminoid substance to be transformed and also of the physical and chemical conditions of the medium.

During progressive decomposition of meats and fish, the bacterial flora undergoes at times a profound change; some species forming acid, others breaking down proteins into peptones and amino acids, and others to still simpler nitrogenous compounds. It is well known that certain bacteria are able to produce ammonia and hydrogen sulfide; others, indol; still others, trimethylamine. Some species may form all of these compounds, yet others are incapable of producing any deep-seated changes in foods. Unfortunately, it is to the latter group that so many of the food poisoning organisms belong. It is well known that putrefaction is due to anaerobic bacteria alone. While it may be found that a certain sample or kind of meat or fish, while undergoing spoilage, usually gives a test for hydrogen sulfide, this is not invariable. The researches of Hoffstadt,[7] Weinzirl and Newton,[8] Cary,[9] LeFevre,[10] and Brewer[11] show that meat is often grossly contaminated with bacteria, but that there appears to be no clear-cut correlation between the quality of the meat and the bacterial count. The Weinzirl[12] anaerobic spore test is useful, and Hoffstadt states that the presence of proteolytic anaerobes is a definite way by which the keeping qualities of meat can be predicted. Aside from the anaerobic spore test and total counts of bacteria, little of value has been obtained by bacteriological means.

Biochemical tests for the detection of decomposition in meats, fish and shellfish have been investigated to some extent. Arbenz,[13] working with the degree of oxygen consumption and the methylene blue reduction test, has found these determinations of value particularly when the meat is in the later stages of spoilage. The various methods

of determining the amino acid nitrogen to indicate the stage of decomposition in meats and fish were investigated by Luttge and von Mertz,[14] Ottolenghi,[15] Waksman and Lomanitz,[16] and Hoagland.[17] The pH value of the serum using the quinhydrone electrode has been used by Herzner and Mann.[18] Eber,[19] Richardson,[20] Sears,[21] and Falk, Baumann and McGuire[22] made ammonia, purine nitrogen determinations and studied other nitrogenous fractions in fresh and spoiled meats. Falk and McGuire[22a] concluded that it was necessary to know the history of the sample in order to interpret correctly the chemical data. They discovered that the amount of ammonia present in a given sample of meat was much greater at the time of spoilage if the meat had been kept at a low temperature than if it had been stored at a higher temperature. This difference they attributed to autolysis. Clough,[23] working with salmon, concluded that although the determination of indol could not supplant odor and physical appearance in the examination of canned salmon, indol afforded a valuable check on the organoleptic test. Hunter and Harrison[24] have demonstrated that the pH is a valuable clew in detecting spoilage in oysters, but Hunter and Linden[25] found no correlation between quality and bacterial count.

Weaver's work,[26] using the production of hydrogen sulfide after the incubation of the meat in nutrient broth as an indication of incipient spoilage, is the most outstanding of the past 2 years. Weaver used meats spoiled under controlled conditions, and there is a possibility that meat spoiled in commercial refrigerators or display cases may not always be polluted with hydrogen sulfide producing bacteria. Korff[27] has found that although the hydrogen sulfide test is a valuable aid, some samples of meat do not produce hydrogen sulfide even when undoubtedly decomposed. These data check Almy's results[28] on canned fish. Weaver found that more of the organisms in fresh meat reduced methylene blue than of those in putrefying meat, but concluded the hydrogen sulfide test to be of more value than the methylene blue reduction. Kerr[29] has found that the normal ratio of water to protein in meats is 1:4. Variations from this ratio may indicate either loss of nitrogen or the addition of water.

Tillmans, Hirsch and Kuhn[30] recently reported careful studies on spoiled meat products, using the meat serum for their tests. They found an increase in volatile acids in the distillate from the dilute acidified serum. They likewise state that a positive isonitrile reaction furnishes an indication of incipient decomposition. Horowitz-Wlassowa[31] has just reported that pH, acidity of the meat extract, refractive index, biuret reaction, total nitrogen or iodine absorption value, give no indication as to freshness of meat. However, the heating of

aqueous meat extract with magnesium oxide for 5 minutes at 50° C. liberates ammonia from ammonium salts, but not from proteins. Litmus paper will detect as little as 0.02 per cent of ammonia. Fresh meat does not give a positive test. Katrandjieff[32] made a very thorough study of the use of the iodine absorption test. He found it of value in detecting spoiled meats.

References could be multiplied, but sufficient evidence has been adduced to show that progress is being made. It is to be hoped that further researches along these lines will be carried out. If simple, rapid, laboratory or field tests for the detection of incipient decomposition in meats, fish and shellfish can be devised, they will be of untold value not only to the public health laboratory worker or field inspector but to the handlers of these products and the general public as well.

Fruits, Vegetables and Their Products*

IN the last report of your Committee on Nutritional Problems,[1] emphasis was laid on the importance of conserving, as far as possible, the vitamin content of foods, and it was stated that the optimum amount of vitamins for health is probably far greater than the minimum amount necessary to afford protection from deficiency diseases. Recognizing the correctness of that committee's views, we would suggest the need of a thorough study of the comparative nutritive value and vitamin content of tree or vine-ripened fruits and vegetables and those gathered while still under-ripe, as an increasing proportion of raw fruits and vegetables are now harvested and ripened under artificial conditions. We understand that the Bureau of Chemistry and Soils, U. S. Department of Agriculture, is now undertaking such a study.

The artificial ripening and coloration of fruits and vegetables is a subject that is being given much attention by growers' organizations and by federal and state agricultural experts. It appears to be impossible to supply some vine or tree-ripened fruits and vegetables to the larger centers of population without such great losses or expense as to make their use almost prohibitive. Recently the use of ethylene gas, and other unsaturated hydrocarbons, has been found to be more effective for the purpose of ripening than the heat treatment previously used, particularly for citrus fruits and tomatoes. Work done on this subject by Rosa[2] at the University of California on three varieties of tomatoes, using low concentrations of gas, indicates the following:

1. Development of red color takes place in about half the time required when ripened in air in the usual way.

2. In comparing vine-ripened, air-ripened and ethylene-ripened tomatoes, vine-ripened fruits were highest in sugar and low in acids; air-ripened fruits had no more sugar than green tomatoes and were high in acid, and while ethylene-ripened fruits were low in sugar, their acid content was about the same as that of the vine-ripened fruit.

3. Although tomatoes artificially ripened, either in air or ethylene, remain firm much longer, they contain less soluble solids than in vine-ripened tomatoes, but much more than the green fruit when picked.

A study of ripening of cranberries made recently at the Massachusetts Agricultural College showed that vine-ripened cranberries con-

* Report of the Committee, presented to the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

tained more sugar and slightly less acid and pectin than those picked when 25 per cent to 50 per cent colored, as is usually done. Vine-ripened cranberries are likewise better colored and flavored.

In commenting on this new process for artificial coloration, the editor of the *Journal of the American Medical Association*[3] calls attention to the fact that while artificial coloring of immature fruit is prohibited under the Food and Drugs Act, some citrus fruits still appear green after they are fairly mature, judged by certain chemical standards of sugar and acid content, and work on coloring such fruit has been undertaken with official state and federal coöperation. The work of Chace and Church[4] indicates that the ethylene treatment produces no change in chemical composition, even though the respiratory rate of the fruit is increased by such treatment. Since citrus fruits are now widely recommended and prescribed for infants and invalids, as the editorial states, and ethylene-treated fruit may be entirely wholesome, work on the comparative vitamin content of artificially ripened fruits and vegetables and further information on the action of ethylene on their chemical composition and nutritive value seem desirable.

In Mexico, Cuba and the British West Indies the growing of raw fruits and vegetables for United States markets has developed very rapidly, so that some of them are now available practically the year around. For instance, the imports for consumption of raw tomatoes from those countries increased from about 52,000,000 pounds in 1922–23 to about 125,000,000 pounds in 1926–27. This year-round availability of raw fruits and vegetables has been largely a development of the past seven or eight years.

Considerable attention is being given to the preparation and preservation of fruit and vegetable juices. A new process for sterilizing fruit and vegetable juices has recently been patented, which depends on the destruction of bacteria, yeasts and molds, which may be present in the juice, by passing the warmed juice between electrodes. By subjecting it to a mild electric current, it is claimed that complete sterilization is effected. The preservation of citrus fruit juices by freezing is being tried out in a small way, with considerable prospect of commercial success.

The committee report last year was entitled "Canned Foods and the Public Health." Since that report was presented, further steps have been taken by the canning industry to insure the wholesomeness of canned foods. For fifteen years, the Research Laboratories of the National Canners Association have been giving a great deal of study to the problem of determining the nature and heat resistance of organ-

isms that may cause spoilage of canned vegetables and other canned foods, and the working out of adequate sterilizing processes for such foods. As a logical sequence to those studies, the laboratories are extending their study to investigating the sources from which such organisms get into canning plants and points in the machinery and equipment which may be favorable to their growth and multiplication. Having secured this information, it is a comparatively simple matter to change the equipment or otherwise alter conditions that tend to introduce spoilage organisms into canned products.

To facilitate this work and to enable the laboratory to cover as much ground as possible during the short canning season, a complete field laboratory for the bacteriological, chemical and technological work necessary has been installed in an autotruck, in which the corn and pea canneries of the east and middle west were visited last summer. It is expected that danger of excessive bacterial contamination of canned foods at some step of the canning process will be detected, and the trouble removed before spoilage occurs. The work has already thrown light on sources of bacterial contamination in canning plants and has made it possible to eliminate them.

Considerable alarm has recently been felt, by food and health officials, both in this country and abroad, over the shipment from the United States and Canada of fruits which have been sprayed with arsenical sprays. Satisfactory methods for the removal of the residues from such spray have now been worked out by the fruit growers in cooperation with the federal and state agricultural departments.

Quite recently the development of a new method of packing canned vegetables in tin or glass, the so-called waterless pack, has been undertaken. In this method the addition of water in the form of weak brine is omitted, the natural juices and the small amount of water retained on the washed and blanched vegetables being all that is required for the sterilizing process. Most of the air is removed from the can mechanically before sealing, to insure a high vacuum and provide the necessary atmosphere of steam in the can for proper sterilization.

It is claimed that this method of packing vegetables improves the flavor and appearance of the product and prevents the waste of valuable nutrients, which occurs when the liquid in which canned vegetables are ordinarily packed is discarded, as is the practice of some consumers. This method is still in the experimental stage, but the prospects are, at least, encouraging.

Certain canned products, particularly corn, after a period of storage sometimes develop discoloration varying in color from brown to

black. The discoloration may occur over any part of the surface of the container in the form of dark patches or in the contents. This defect is not confined to corn, but probably has caused more trouble in this product than in any other canned food. It also occurs with such products as shrimp, lobster, flaked fish, okra, onions and hominy. When certain canned foods are subjected to the high temperature necessary for sterilization, sulphur compounds are set free from the protein in the food, and these compounds may combine with the metal of the can to form black iron sulphide mixed with some brown tin sulphide. In the case of onions the source of sulphur is largely the volatile oils which give the onion its distinctive flavor. These dark substances are not injurious to health and no objection can be made to them except from the standpoint of the unsightly appearance which they give the container and product. The problem of such discoloration in vegetables has recently been solved by the development of a lacquer lining for cans, which overcomes this trouble. A small amount of zinc oxide is suspended in the lacquer, and the sulphur combines with the zinc, forming insoluble white zinc sulphide, instead of black iron sulphide. In the case of sea foods, the discoloration of the food is avoided by a paper or parchment lining inside the can.

Your committee has endeavored in this report to point out briefly some of the recent progress made in the manufacture and preservation of fruits and vegetables and their products. The subjects covered, we believe, are of particular interest to those concerned with the public health.

Maternity Premiums in France

IN 1928 arrangements for paying maternity premiums were in force in 30,353 communes in 82 out of the 90 Departments of France. The average amount of these premiums, paid by the department to poor women at the birth of a child, was 300 francs, to which varying amounts, from 50 francs up, were added by the communes. These premiums are not provided by a National law, but by departmental or municipal regulations.—*Le Nourrisson*, Paris, Jan., 1929, p. xiii.

Hospital and Clinic Services

THE policy of the Committee on Administrative Practice of the American Public Health Association as defined by its Sub-Committee on the Organized Care of the Sick, and approved by the general committee last year, includes in the field service of the committee, the study of the community relationships of hospitals, clinics, and other facilities for the organized care of the sick, making clear that the administrative affairs of the institutions and their professional standards are regarded as properly belonging to other organizations in this field, and not to the American Public Health Association.

This policy has been recently carried out in surveys, under the committee's auspices, in St. Louis, Mo., Cincinnati, O., and Monmouth County, N. J., and it is anticipated will lead to the definition of schedules and forms of information concerning the services for the organized care of the sick, and possibly at a later date to criteria for their appraisal from the community and public health standpoint.

Reports presented at the Cincinnati meeting of the American Public Health Association, and other material, have shown the increasingly close relations existing between hospitals, clinics and health departments and voluntary health agencies in many communities.

Questions frequently arising are: How shall the sufficiency of service for the organized care of the sick—from the standpoint of community and public health interests—be judged? What facts need to be known for intelligent consideration of this matter?

The Sub-Committee on Organized Care of the Sick has thought it would be helpful to the public health field generally, to suggest and outline tentatively a few specific questions which those connected with official and voluntary health work should have in mind in considering these organized curative facilities.

The field service of the committee is frequently asked to advise or give information concerning new facilities which are contemplated in communities of various sizes and with different problems. Obviously, such advice can be little more than a guess unrelated to local needs unless a comprehensive statement of existing conditions is available. It is to help public health workers and others to visualize the essential facts necessary to reach decisions of adequacy both in quantity and type that these questions have been prepared. Though numerous questions more or less interesting will suggest themselves to the reader

as desirable additions to the list, the committee has rigorously kept to those items dealing with the subject in a broad way in order that this list would not be too long for helpful and effective use by a large number of health administrators.

COMMITTEE ON ORGANIZED CARE OF THE SICK

MICHAEL M. DAVIS, PH.D., *Chairman*

GEORGE C. RUHLAND, M.D.
HAVEN EMERSON, M.D.
D. L. RICHARDSON, M.D.
W. S. RANKIN, M.D.
WILLIAM J. NORTON
W. C. RUCKER, M.D.

TWENTY-FIVE QUESTIONS WHICH PUBLIC HEALTH PEOPLE SHOULD ASK ABOUT HOSPITALS AND CLINICS IN THEIR COMMUNITY

1. What hospitals are there in your community for the care of the sick (medical, surgical, obstetrical, children's diseases, etc.)?
   a. Total number of hospitals
   b. Hospitals supported primarily by taxes (city, county, state, federal)
   c. Privately supported hospitals not managed for profit *
   d. Proprietary hospitals (run for profit)*
2. How many beds † in these institutions?
   a. Total number
   b. Tax supported
   c. Privately supported
   d. Proprietary
3. What is the number of hospital beds per 1,000 population (all hospitals)?
4. What was the total number of days' care furnished by the hospitals last year? What percentage was this of the total possible hospital bed days?
   a. Number in all hospitals together
      Percentage of maximum possible
   b. Each hospital separately
5. What number of bed days' care was furnished last year to patients living outside the community? What percentage was this of the total bed days' care furnished?
   a. In all hospitals together
      Percentage of total days
   b. Each hospital separately
6. What was the number of free hospital days' care given? What percentage was this of the total days' care?
   a. All hospitals
   b. Hospitals individually

* Privately supported hospitals not managed for profit include hospitals maintained by charitable or religious corporations or by industry; in general, all hospitals which are managed for the service of the public or for some section of the community and from whose operation no individual derives financial support. Proprietary hospitals are institutions incorporated as business enterprises and run for profit, or unincorporated hospitals run by individuals for profit.

† Beds should be taken to include bassinets for babies. It is desirable to state the number of bassinets separately, in addition to giving the total beds including bassinets.

7. How are hospitals in your community rated by the American College of Surgeons and the American Medical Association (specify for each hospital)?

8. Which of the hospitals maintain out-patient departments (dispensaries)?

9. What other clinics which treat ambulatory cases of disease but which are not connected with hospitals exist in your community?

10. What was the number of visits to clinics last year?

a. To the out-patient departments of hospitals
b. To all other clinics
c. Total visits

11. How many clinics, conferences and classes of public health interest are maintained (tuberculosis, venereal disease, prenatal, infant, preschool, mental hygiene, child guidance, heart, cancer, health examination)?

a. In out-patient departments of hospitals
b. By the health department
c. By other agencies outside the hospitals or health department
d. Number of visits to all these clinics last year

12. What were the total current expenses of the hospitals in the community last year?

a. For tax supported hospitals
b. For other hospitals
c. Total

13. What was the total income to the hospitals from patients? What proportion did this bear to the total current income of the hospitals from all sources?

a. Tax supported hospitals:
   Income from patients
   Percentage of total current income
b. Other hospitals:
   Income from patients
   Percentage of total current income

14. What was the investment by the community during the last 5 years in new hospital buildings or permanent improvements in existing buildings?

a. From tax funds
b. From private funds

15. What was the per capita cost per day's care last year for the hospitals of the community (include out of town patients in considering per capita cost)?

a. All hospitals
b. Hospitals individually

16. Which hospitals and clinics have organized social service departments?

17. How many beds are available for the isolation and care of acute communicable diseases (diphtheria, scarlet fever, smallpox, measles)?

a. In general hospitals
b. In special hospitals
c. Total beds

18. How many beds for the care of tuberculosis exist in your community, or are accessible?

a. General hospitals

b. Special hospitals or sanatoriums
c. Total beds
d. Number of beds per 100 deaths from tuberculosis (3-year average)

19. How many beds for the care of mental disease cases exist in your community, or are accessible?

a. In tax supported hospitals
b. In privately supported hospitals
c. In proprietary hospitals
d. Total beds

20. How many institutions furnishing convalescent care (including medical service) exist in your community? How many beds are thus provided?

a. Tax supported institutions
Number of beds
b. Privately supported institutions
Number of beds
c. Proprietary institutions
Number of beds
d. Total

21. How many institutions are provided for chronic * illness (including medical service)?

a. Tax supported institutions
Number of beds
b. Privately supported institutions
Number of beds
c. Proprietary institutions
Number of beds
d. Total

22. How many of the physicians in your community have the privilege of hospitalizing and treating cases in local hospitals? What percentage is this of all the physicians in your community?

23. How many diagnostic and pathological laboratories are generally available to the medical profession in the community? Which laboratories include X-ray service?

a. In hospitals
b. By the health department
c. By other agencies

24. In what per cent of all deaths occurring in local hospitals last year was post-mortem examination made?

25. What organizations in your community furnish bedside nursing care?

a. All organizations
Budget
Patients cared for
Number of visits
b. Each organization separately

* A chronic patient is defined as a person who has been or is likely to be incapacitated by disease for a period of 3 months, who needs medical or nursing care, and in whom incapacity will probably continue for an uncertain period.

Care of Communicable Diseases in General Hospitals*

DENNETT L. RICHARDSON, M. D.

City Hospital, Providence, R. I.

NO LONGER ago than 1860 it was learned through a questionnaire from the London Fever Hospital that 11 general hospitals in London admitted a limited number of patients sick with contagious diseases, in 5 of which they were admitted to the general wards, and in 6 of which separate wards were set aside for their care. It was also learned that of 20 general hospitals throughout England 9 refused fever cases, 5 distributed them in the general wards and 6 maintained separate wards for them. At that time a spirited discussion was going on in London as to whether it was safer for patients and hospital personnel to treat contagious diseases in general hospitals or in special hospitals set aside for their care.

Those who claimed that it was safer to care for contagious diseases in general hospitals than in isolation hospitals reasoned that if not too many contagious patients were admitted the infection would be diluted, whereas in hospitals devoted to contagious diseases alone it would be more concentrated, and therefore more danger would exist for patients and hospital personnel. However, further investigation of the number of cross infections and the amount of illness among members of hospital staffs revealed that both were actually less in the London Fever Hospital than in general hospitals in which contagious patients were cared for. It should be remembered, however, that it was not until some fifteen or twenty years later that Pasteur, Koch and other investigators discovered disease producing germs, and in the light of our present knowledge the conclusions arrived at in the London investigations were well founded as conditions existed in 1860.

These studies led to the construction of isolation hospitals on a rather widespread scale and of a permanent character. The London Smallpox Hospital had been established in 1745, the Lock Hospital for Venereal Diseases in 1746 and the London Fever Hospital in 1802. With these and a few other exceptions, previous isolation buildings

* Read before the Health Officers Section of the American Public Health Association, at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

had been built for leprosy, which was very prevalent in Europe about the 15th century, epidemics of smallpox, cholera, plague and typhus fever. For the most part they were of temporary construction and were buildings for the segregation of these patients rather than hospitals in the modern sense.

We have seen even up to the present time a survival of this idea of segregation and crowding in hospitals for contagious patients, and the lack of clinical laboratories, X-ray and other diagnostic and treatment facilities with which every general hospital is provided. There has been no better example of this attitude in the United States than the proverbial pest house. It is only recently that a real interest in the treatment of contagious diseases has been shown.

Up to 1860 hospitalization of such diseases as scarlet fever, diphtheria, measles, whooping cough, etc., had been carried on to a limited extent. About this time England was suffering from a very severe outbreak of scarlet fever attended by a high fatality rate and, in fact, it was this epidemic that was largely responsible for the 1860 investigations. There followed in the British Isles an intensive building program of isolation hospitals, and by 1890, in a considerable number of English and Scottish cities, as many as 90 per cent of patients sick with diphtheria and scarlet fever were cared for in special hospitals. In this country among the earliest isolation hospitals to be established were the Philadelphia Hospital for Contagious Diseases built in 1865, the Willard Parker Hospital in 1884 and the Boston City Hospital wards in 1895.

The facts concerning the modes of transmission of infectious diseases learned during the last thirty years have led to revolutionary changes in methods to control them both in the community and in the hospital. Previous to the discovery of disease producing germs, ideas about the modes of transmission were vague, and efforts to control them either were nonexistent or were very crude. The discovery of disease producing germs ushered in a new period during which atmospheric transmission was looked upon as a great factor in their dissemination because these germs could sometimes be recovered from the air in contagious disease hospitals and elsewhere.

The first investigations which led to the correction of the idea of the importance of atmospheric transmission were carried on in the Hospital for Sick Children, in Paris, by Grancher. During a 10-year period, beginning in 1890, he admitted in the general wards of this hospital a limited number of contagious disease patients. Each bed was surrounded by a wire screen to keep the patient from contact with those suffering from other diseases. Within this enclosure were kept

the nursing utensils, which were sterilized on removal, and also gowns and washbasins in which doctors and nurses washed their hands after caring for the patient. Grancher conclusively demonstrated that scarlet fever, diphtheria and measles were rarely carried through the air.

From this study resulted the construction of the Pasteur Hospital in Paris, which was the first to isolate in different rooms on the same ward floor different kinds of infectious diseases. Atmospheric transmission was disregarded. In this hospital painstaking care was exercised to prevent both direct and indirect contact. The cross-infection rate since it was established in 1900 has been about 1 per cent. Very soon the introduction of this method into England followed and a little later it was introduced into this country.

It has been found that, of the infectious diseases, cross-infections of measles and chicken pox are more numerous than with others, and yet low enough to make the method practicable if the technic is rigidly enforced.

Our experience with this method at the Providence City Hospital over a period of 18 years is presented here in tables. The total number of various diseases cared for during this period will be found in Table I.

TABLE I

PROVIDENCE CITY HOSPITAL
CONTAGIOUS DISEASES

1910–1927

Disease	Cases	Disease	Cases
Anthrax	3	Pneumonia	276

NOTE: While general hospitals do not publish or rarely keep track of the number of contagious diseases occurring in their wards, I believe that the rates just presented compare favorably for general hospitals in which children are cared for.

transmission of infectious diseases is having a very great effect on the methods employed in the further control in the community. Fumigation, which only a few years ago was practiced everywhere, has been almost entirely given up because Dr. Chapin found that it was unnecessary. Likewise, the knowledge that the common infectious diseases found in this country are communicated through contact and not through the atmosphere, is bringing about revolutionary changes in isolation hospital administration.

Since it is evident that several different infectious diseases can, with reasonable safety, be cared for on a single ward floor, it makes it feasible for the smaller cities and even the larger towns to provide hospital accommodation for them. Formerly it would have been impossible because of expense, since a separate ward at least would have had to be provided for each disease. The whole country will be benefitted by a more widespread availability of accommodation for infectious diseases, both from the standpoint of preventing their dissemination and, equally important, of the better care which the patients will receive.

Satisfactory hospitalization of infectious diseases should include

the very best medical and nursing care at the least possible expense. It is well recognized by hospital administrators that the most efficient hospitals are neither too large nor too small. It is quite possible for cities like New York, Boston, Philadelphia, Chicago and other large cities to build and maintain special isolation hospitals, modernly equipped and adequately staffed at reasonable cost. But in cities, counties and towns of less than 100,000 population it is advisable, wherever possible, to locate wards for infectious diseases on the grounds of some well equipped and well staffed general hospital.

There are several reasons which justify this recommendation. In a general hospital, to have close at hand wards for the care of infectious diseases in which can be isolated cases which develop among patients, nurses and other hospital personnel, is a great help and comfort. Very often patients sent to general hospitals are found to be suffering from some infectious disease or at least are very suspicious cases. Not infrequently operative conditions occur in patients who are ill with or convalescent from some infectious disease. It is much

276 previously had diphtheria
1,499 previously had measles

less embarrassing to transfer them to isolation wards in the same hospital than to be obliged to send them home or to some isolation hospital. Moreover, there are several acute diseases such as typhoid fever, pneumonia, meningitis, acute throat conditions, transmissible skin diseases, etc., commonly admitted to general hospitals, which can be cared for with better success and safety in wards set apart for infectious diseases, than by distributing them in wards in which non-infectious diseases are cared for. By utilizing some of the isolation wards for acute infections with a low degree of transmissibility, and other wards for the more highly transmissible diseases, a hospital will be prepared to furnish better medical and nursing care, and both patients and hospital employes will be much better protected.

During the World War the army medical and nursing services found it impossible to locate a sufficient number of doctors and nurses who had had any training in infectious diseases and in isolation hospital administration. It is a training which is extremely important to every physician and nurse. Much interest is now being shown in this training and more and more hospital training schools are acquiring affiliations with isolation hospitals. But these hospitals are too few in number to provide such teaching to all physicians and nurses; but should general hospitals throughout the country, so far as community needs require, build and maintain isolation wards, this type of training would become available to a greatly increased number of internes and nurses.

From the standpoint of service, patients ill with infectious diseases are much better off than in small isolation hospitals. General hospitals are usually staffed by the best specialists in the community and their services would be more promptly and regularly available. Likewise, general hospitals are now well supplied with nurses, and patients would receive more attention than is provided in many isolation hospitals. The X-ray department, the surgical department, the dietetic department, good laboratories, etc., with which every recognized general hospital must now be equipped, would help to insure the best possible care of contagious disease patients.

For these several reasons it seems rational to recommend, except in very large cities, that infectious diseases be cared for in wards operated in connection with general hospitals. The only essential requisite is that the isolation wards be under the supervision of a resident physician who has had experience in a modern contagious hospital, and that the nursing be in charge of a graduate nurse skilled in the nursing care of infectious diseases and in the technic necessary to prevent the spread of infection in a hospital.

DISCUSSION

W. S. Rankin, M.D., Duke Endowment, Charlotte, N. C.—As Dr. Richardson has brought out very well, this new idea of treating infectious diseases in the specially designed wards of general hospitals has resulted from changing our idea from atmospheric infection to the infection by things and persons, as has been so well preached in this country by Dr. Chapin.

Dr. Richardson limits his recommendation of these wards for the treatment of infectious diseases in connection with general hospitals to the smaller communities of this country, because in the larger cities the advantage of special hospitals for the treatment of contagious diseases is well recognized.

The advantages of this method to the smaller communities and cities of 100,000 population and less might be summarized as follows: First, the patient with an infectious disease has the advantage in a general hospital of more adequate diagnostic and treatment facilities with reference to both personnel and equipment, such as laboratories, dietetic department, and X-rays. The resources there are more abundant and more varied than could be found in a general hospital. That is the advantage to the patient.

Second, there is a distinct advantage to the nurse, in the matter of training. Most nurses are trained in the general hospitals of this country, and unless those general hospitals have departments for treatment of contagious diseases, the larger percentage of nurses fails to receive training in this most important branch of nursing. Another advantage to the nurses is the professional technic attained, for dealing with contagious diseases brings about a refinement of technic and a higher ideal of cleanliness than they would otherwise have.

Third, the advantages to the doctors: The majority of internes are now serving in general hospitals where they acquire no experience in the treatment and handling of contagious diseases. Their interest in contagious diseases is, therefore, less than it would be if they were more intimately associated with this problem in their earlier years. Those who are interested in tuberculosis have come to the conclusion in recent years that the too far separation of the problem of tuberculosis from that of the general practitioner has not resulted in the greatest good to the largest number. Tuberculosis has been so far separated in its treatment from the general problems of medicine that many of the doctors of this country have ceased to think of tuberculosis as a part of their work; and the tendency now, and a tendency promoted by the leaders in the movement of tuberculosis work, is to bring the problem back closer to the general practitioner, in order to bring about new interest and develop and renew his interest in the problem. This same principle applies to this problem of contagious diseases. If we are to preach here isolation of the treatment of contagious disease, a thing separate and apart from general medicine, general medicine will more and more lose its interest in contagious disease, feeling more and more that it is somebody else's problem, a problem of the specialist. So, this bringing together of this special problem with the general problem of medicine in these general hospitals does the two things—it permits the training of internes in the treatment of contagious diseases and it develops a larger and deeper interest on the part of medicine in general in this group of diseases.

For more than half the population of the United States, unless this principle has the endorsement of leaders in public health work and in medicine, it becomes more or less impossible to develop any sort of hospital facilities for the treatment

of contagious diseases, because cities of 100,000 population and less cannot be expected to have special hospitals for contagious diseases, because many of these places have no general hospital.

Haven Emerson, M.D., New York, N. Y.—The advice of Dr. Richardson, though preëminently important for the smaller communities, is a matter of very great economic consideration to the larger cities as well. Not more than 14 per cent of the beds for contagious diseases in large cities of the country are actually occupied by communicable diseases during the year now. That was the report for 100 cities in the United States of the year 1925, and there is no reason to believe the situation has improved since that time.

Charles V. Craster, M.D., Newark, N. J.—I am just wondering whether those special hospitals with empty beds could not be used for the treatment of ordinary medical and surgical cases. Why should these hospitals be empty? If contagious diseases can be handled in the general hospital, why should not other diseases be handled in an isolation hospital?

Arlington Ailes, M.D., La Salle, Ill.—We have an isolation ward which, as Dr. Emerson points out, has been little used, and the result is that funds to cover its operation have been lowered so that we cannot keep it up adequately; and, as a result, a vicious circle has been established. The number of patients being sent there has been reduced because we cannot keep it up. A certain hospital wants to take it over for a nurses' home, and build an addition to the hospital to take care of communicable diseases, but they hesitate on this matter of admitting smallpox cases. I would like to know whether I can go back to those people and recommend that they can safely admit, into the general hospital, smallpox cases.

James A. Hayne, M.D., Columbia, S. C.—I would like to say that as far as that policy is advocated, the Roper Hospital in Charleston which is one of the oldest in the country has always pursued the plan of taking the smallpox cases, scarlet fever or any others, including tuberculous patients, and it is still pursuing that policy.

E. L. Bishop, M.D., Nashville, Tenn.—I should like to ask Dr. Richardson to define his generalization for the size of the communities. I would like to know what he believes is the dividing zone.

Dr. Richardson—In reply to Dr. Bishop's question, if I understood it correctly, we arbitrarily selected the size of the community as 100,000. A community of that size should have isolation hospital facilities of something like 150 beds. I mean, particularly, if the isolation hospital is going to be required to accept various kinds of infectious diseases, that a hospital of 150 beds or less is not economical to maintain. There are many of the smaller isolation hospitals in the country that are not only empty part of the year, but are empty for even a year or two at a time. So far economic reasons a hospital of, say, less than 150 beds should not be maintained as a separate institution. I think perhaps even a higher figure ought to be set.

In Providence we have admitted smallpox cases since about 1912 or 1914. Since the pesthouse was done away with by fire, to make way for a railway extension, we have admitted these cases to our best equipped isolation ward, in which we very often have private patients. The only precaution we take is that we always keep our nurses and hospital personnel vaccinated up to date, and at the time the patient is admitted to the ward we vaccinate all patients in that ward. We have not made a practice of vaccinating patients in other wards.

I just want to stress one other thing, and it is this: By 1890, London and

some of the other English cities admitted as many as 90 per cent of the two diseases, scarlet fever and diphtheria. When they began this building program in the 70's, they hoped to stamp out those two diseases by hospitalization. The result has been that even though they have hospitalized 90 per cent of the recognized cases of diphtheria and scarlet fever, both these diseases are just as prevalent as they ever were. It might be fair to say the mortality has greatly decreased.

But it is perfectly obvious that hospitalization alone is never going to stamp out infectious diseases, and that isolation is not the only function of an isolation hospital. It should be a place where patients who cannot receive the proper attention at home, and who live under circumstances where isolation cannot be carried out properly, are admitted to the hospital not only with the idea of isolation, but of giving them the very best possible treatment. This idea has not always been carried out in this country or in Europe.

I want to stress one other thing. By admitting a large variety of diseases, particularly diseases common all the year around, or even more common in the summer, you can keep your hospital beds much better occupied than if you keep seasonal infectious diseases.

Harmon Publicity Awards

THE Harmon Foundation, in consultation with the Social Work Publicity Council, offers four awards of $100 each for a complete record of a well planned and executed program covering a year's work in publicity carried on by a public or private agency engaged in social or health work. These will be as follows: $100 for the best record submitted by a national agency; $100 for the best record submitted by a state or regional agency (a regional agency is here taken to mean an agency in any geographical grouping not otherwise specified); $100 for the best record submitted by an agency in a city or county of 200,000 or more population; and $100 for the best record submitted by an agency in a city or county of less than 200,000 population.

In addition to the above awards for a year's publicity record the Harmon Foundation, in consultation with the Social Work Publicity Council, also offers awards for unpublished articles on social work. These are $300, $200 and awards of $50 each, to go for the best unpublished articles in which social work is popularly presented with a view to publication in a magazine of general circulation.

Write Harmon Foundation, 140 Nassau St., New York, N. Y., for conditions.

Cereals and Their Products*

THE Committee on Cereals and their Products was added to our list of standing committees at our Buffalo meeting, held in 1926. Since no report was submitted last year, it seems desirable at this time to advance certain suggestions relative to the types of reports which should be rendered and also to indicate subjects which merit consideration. Since the primary object of our Section is to consider foods from the public health point of view, it is obvious that our survey of the cereal field should stress the food value of these materials, consider their keeping qualities or freedom from deteriorative and even harmful changes, gather information on their combination with other foods, summarize our present scientific knowledge of their place in our food economy, study the effect of manufacturing processes on their value as foods, stimulate research, and, finally, should present a fair evaluation of these food substances in the light of the available scientific evidence.

Such a program should produce a series of reports of value to those interested in the food and nutrition field and also to manufacturers and distributors directly concerned with these commodities.

With the foregoing principles in mind, we believe the following subjects are worthy of study:

1. The nutritional value of bread
2. The protein value of cereals
3. The vitamin content of cereals
4. The germ of cereals
5. The value of cereal bran
6. The deterioration of cereals
7. The mineral content of cereals
8. Manufactured or prepared cereals
9. Cereal breakfast foods
10. Sanitation of cereals and cereal products

For this year's report we have chosen the nutritional value of bread, for the reason that bread plays such an important rôle in our diet. Further, bread itself and the various ingredients entering into its composition have long been the objects of scientific study, especially with each new advance in the science of nutrition.

A critical review of the earlier contributions in the study of bread

* Report of the Committee, presented to the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

and bread components will not be undertaken since these are adequately covered by the more recent books in the food and nutrition field. Instead it has seemed advisable to confine our discussion to the contributions of the past seven or eight years and to note the present status of our scientific opinion on the nutritional value of this important foodstuff.

In order to indicate the magnitude of our bread consumption, recent statistics may be of interest:

The production of flour required for consumption in our country amounts to approximately 107,000,000 barrels per annum.

Of this amount nearly 5,000,000 barrels are used by biscuit and cracker manufacturers, somewhat over 2,000,000 bbl. by the macaroni industry and 10,000,000 bbl. for self-rising flour, leaving a little over 90,000,000 bbl. available for bread, cake, pastry, etc., made by bakers, hotels, restaurants and in the home. According to the 1925 reports of the U. S. Bureau of the Census, the baking industry used 40,500,000 bbl. of flour for all purposes. This includes 37,700,000 bbl. of wheat flour and 2,800,000 bbl. of rye and other flours. The amount of wheat flour used in the home, restaurants and hotels is therefore approximately 52,000,000 bbl. Of this quantity, approximately one-half is used for bread and one-half for pastry and other purposes, indicating that 26,000,000 bbl. are consumed for bread by these agencies. Of the bakers' wheat flour supply, fully 80 per cent is for bread and totals 29,000,000 bbl. Therefore the total flour used for bread by all agencies reaches 55,000,000 bbl. per annum.

The rôle of bread in nutrition is important since it furnishes about 40 per cent of our total calories and about 30 per cent of the total proteins.

In a symposium on bread held by the American Chemical Society in 1923, two important papers on the nutritional value of bread were presented. In one of these Hale[1] presented the results of animal experimentation with commercial white bread, commercial whole wheat bread, and a special bread made with wheat flour, whole milk, a wheat embryo extract, and added calcium. In the case of both the commercial white and whole wheat breads, with one exception, in all his series, they were very deficient from the standpoint of securing adequate nutrition from a single food substance. The exception was with a bread actually made from whole wheat. He pointed out further that most so-called whole wheat flour is a degerminated and partially decorticated flour. The special bread gave results in excellent agreement with those obtained by feeding his rats on normal food.

Hoffman[2] made an exhaustive study of the reproduction of animals

on an exclusive diet of bread which was of the same type as the special bread used by Hale. He obtained normal growth, health and reproduction with both mice and rats when reared on this bread and water. Observations on children fed this bread confirmed the results of the animal experimentation.

In an article published in 1925, Wood,[3] of Cambridge, asks the question whether "modern white bread is a worse food than bread made from stone-ground flour." He pointed out that bread protein is fairly well digested, that bread contains only a small proportion of fat and ash, the latter also being poor in phosphorus and calcium. The Cambridge experiments showed that 96 per cent of the calories contained in bread made from patent flour were digestible whereas 90 per cent were digestible in the breads made from stone-ground flour from which about 12 per cent of bran had been sifted.

Hindhede,[4] the Danish physiologist, showed that bread protein has the same biological value as the protein in meat and milk.

Sherman,[5] in a study of the protein requirement of maintenance in man and the nutritive efficiency of bread protein, stated: "It does not seem necessary to discriminate against bread protein as compared with the protein of staple foods in general in so far as the requirements of adult maintenance alone are concerned."

Eddy[6] has shown that milk added to bread increases the calcium and vitamins and thus reduces the deficiency of white bread in these essentials. Johns, Fink and Jones[7] described the making of a nutritionally balanced bread, utilizing peanut flour or soy bean flour.

Hartwell[8] kept animals on a diet of white bread, butter and a salt mixture for a year without showing symptoms indicative of lack of vitamin B.

Hawk, Smith and Bergeim[9] secured better growth in rats with standard bread to which 5 per cent yeast powder had been added than without this addition. In each experiment the bread was supplemented with butter and a salt mixture, but the growth obtained was below the normal rate.

Miss Gault[10] found that bread made with 6 cakes of yeast to a loaf nourished rats much more effectively than bread made with ½ cake of yeast to a loaf. The extra yeast supplemented both the water-soluble vitamin and the protein.

Nelson and Nelson[11] made a critical study of vitamin B in yeast bread and concluded that "yeast bread, as it is usually made, contains little vitamin B. Rats kept on a diet adequate in all respects except in vitamin B, and containing 75 per cent of yeast bread, failed in all cases and developed polyneuritis."

Swanson[12] states that the mineral deficiency of wheat flour in calcium, phosphorus, sodium and chlorine must be made good by the inclusion of milk and certain vegetables in the diet and that the wheat proteins are best balanced by those from milk, eggs and meat. These balancing foods also supply several of the vitamins.

McCollum and Simmonds[13] express the following opinion:

Whole wheat bread, while superior to the bread made from refined flour, is not so satisfactory a source of the several nutrient principles necessary to make as satisfactory a diet as is a combination of suitable proportions of white flour with either of the protective foods, milk or the leafy vegetables. Therefore it seems logical and sane to assert that the choice of flours may safely be left to the consumer, provided there is a full understanding of the necessary precautions in the selection of foods.

In an editorial[14] discussion of the subject of "Whole Wheat versus White Bread," Osborne and Mendel[15] are quoted as follows:

Whenever bread made from highly milled flour forms an unduly large proportion of the diet of children, the vitamin deficiencies may lead to malnutrition. In this country there is relatively little occasion to be concerned on this score, because the food habits of our people are such as to make cases of this kind comparatively rare.

Summarizing our present knowledge of breads made from white and whole wheat flours, it may be stated that white bread is deficient in vitamins, certain essential minerals, and the protein needs supplementing. Whole wheat bread is also deficient though to a lesser degree and also is not quite so digestible. Both are incomplete foods and require the supplementary use of milk and leafy vegetables. Notwithstanding these shortcomings, bread supplies a very large part of our calorific requirement.

As Eddy[6] has expressed it, "The preëminence of bread in the diets of western nations is recognized as well-justified by dietetic and economic considerations."

MILK IN NUTRITION

WE have commented upon the preliminary report of the tests conducted by the Scottish Board of Health on the feeding of a large number of school children.[1] The results were so important that the experiment was continued, and the second preliminary report is now before us.[2]

The study was carried on at seven centers, the number of children concerned being 1,425. At each center the children were divided into four groups, one of which received whole milk, one separated milk, one a biscuit ration having the caloric value of the separated milk, while the fourth acted as controls, receiving no special diet. The whole milk averaged 3.85 per cent butter fat and the separated milk 0.33 per cent. Measurements were made four times, except at Belfast, where only three were done. The work was carefully controlled and every effort made to obtain accurate average results, taking into consideration the difference between the winter clothing worn at the beginning and the lighter clothing at the end of the study.

The results have more than justified the conclusions drawn from the first set of experiments. For all ages the great value of a milk ration given at school in addition to that used at home was clearly demonstrated. Combining the milk-fed groups, the average increase in height was 1.21 per cent more than in the first test, while the increase in weight was 3.75 per cent greater. In the milk-fed group, all ages combined, the average increase in height was 23.5 per cent, and in weight 45.37 per cent over the non-milk-fed group. Children who took part in both tests showed the benefit of the ration to an even greater extent than in the first test, their improvement continuing over the second year.

An interesting feature is the comparison of the groups receiving separated and whole milk. For most of the groups, there is no "significant" difference, but in the 6-year old group, whole milk gives "significantly" better results for both weight and height. In all groups, those receiving milk, either separated or whole, showed better results than those receiving the biscuit ration or the controls. The difference between those receiving the extra biscuit ration and the controls is practically negligible.

Once again the value of milk has been conclusively shown, and while skimmed milk gave excellent results in the second as well as in the first experiment, it must be remembered that it supplemented a certain amount of milk received by these children at home, and the conditions do not furnish a clear comparison between the value of whole and separated milk. There is no question that whole milk is a more complete food than separated milk, but the experiments certainly demonstrate, as pointed out in the first preliminary report, that the latter is an excellent article of food, and in countries like England, where the expense of whole milk and butter is practically prohibitive to many of the poorer class, it supplies a wholesome and nutritious food, which, supplemented by small amounts of fresh vegetables, makes an adequate diet.

The conclusions drawn from this, as well as other similar investigations, strengthen the opinion that milk is the single most perfect food, and is a primary factor in the growth and nutrition of children. The campaign for the increased use of milk by children and adults alike is based on sound facts. We still need to push our efforts for clean milk, and we should draw a distinction between pasture milk and stall-fed milk, which does not have the same value unless the stall-fed animals are specially dieted.

THE DEATH OF FERNAND WIDAL

Professor Titulaire de la Faculté de Médicine, Paris

THE death of Widal is of more than ordinary importance to laboratory workers as well as physicians on account of the agglutination test with which his name is almost universally coupled. He died from cerebral hemorrhage on January 14 at his home in Paris, and was buried at Montmartre on January 17. He was within less than two months of being 67 years of age.

As a student he showed exceptional ability, and was always attracted by laboratory work. At the age of 27, his treatise on Puerperal Infection was published. He was made professeur agrégé in 1895, and in 1896 announced the agglutination test for the diagnosis of typhoid fever which carried his name to the scientific world. It will be remembered that this test was introduced to Americans in the same year by the late Dr. Wyatt Johnston at the meeting of the American Public Health Association held in Buffalo. An unfortunate controversy took place over the discovery of the agglutination test. Though it was claimed by Widal himself, who gave a demonstration of it in June, 1896, it has been shown that Gruber of Vienna was the pioneer, and that even in publication he was preceded by Durham, who credited it to Gruber. There is no question, however, that to Widal belongs much credit, especially in making it a practical procedure. Even the Germans speak of the "Gruber-Widal" reaction.

Widal's reputation, however, was not dependent upon this work, since, either alone or with Chantemesse, he made notable contributions to cytodiagnosis, antityphoid vaccination, and the influence of sodium chloride upon edema. His publications were noted for clarity and accuracy.

He was one of the best known physicians in Paris, and had a large following of young men, chiefly on account of his clinical work, centered at the Cochin Hospital. He was noted for his excellent organization and his systematic work. He was an unusually good lecturer, speaking without notes, and always attracted a large number of hearers. He was more than usually beloved by his many students, as well as by the public, and was one of the rare men whom the world can ill afford to lose.

Widal was the recipient of many honors from his own country as well as others.

ASSOCIATION NEWS

THE JOURNAL

It is with considerable gratification that the American Public Health Association announces that the editing of the JOURNAL will hereafter be done by M. P. Ravenel, M.D. Dr. Ravenel, a past president of the Association, has been for a long time Chairman of the Editorial Committee of the JOURNAL and has contributed liberally to the editorial and book review sections. Beginning with this issue Dr. Ravenel will review all manuscripts submitted and personally edit all articles for publication. Members and others submitting manuscripts or having other occasion to correspond with the JOURNAL in reference to general editorial matters should address: M. P. Ravenel, M.D., University of Missouri, Columbia, Mo.

Communications or notes relating to the several JOURNAL sections should be addressed to the respective section editors.

Correspondence concerning subscriptions, advertising, reprints or other matters relating to the publication office should be addressed to the Managing Editor of the *American Journal of Public Health and the Nation's Health*, 370 Seventh Avenue, New York, N. Y.

CONNECTICUT PUBLIC HEALTH ASSOCIATION

The following officers were elected at a meeting held in New Haven, January 30: *President*, C. P. Botsford, M.D., Hartford; *Vice-President*, B. N. Pennell, D.V.S., New London; *Secretary-Treasurer*, Richard W. Pullen, M.D., New Britain; *Board of Directors:* B. N. Pennell, D.V.S., New London; L. E. Poole, M.D., Fairfield; G. H. Joslin, M.D., Hamden; M. E. Culver, Middletown; Harriet Leck, Hartford; Elias Pratt, M.D., Torrington; E. H. Metcalf, M.D., Rockville; F. E. Wilcox, M.D., Willimantic.

MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH

At the annual meeting of the Massachusetts Association of Boards of Health held in Boston, January 31, the following were elected officers of the association for the ensuing year: *President*, John J. McGrath, Salem; *First Vice-President*, M. Victor Safford, M.D., Boston; *Second Vice-President*, J. U. Paquin, M.D., New Bedford; *Secretary*, Stephen L. Maloney, Boston; *Treasurer*, Francis G. Curtis, M.D., Newton; *Executive Committee*, E. H. Trowbridge, M.D., Worcester; L. A. Jones, M.D., Norfolk; J. R. Sackett, Springfield; G. H. Lennon, Haverhill; J. R. Glennon, New Bedford.

GEORGIA HEALTH OFFICERS' ASSOCIATION

The Georgia Health Officers' Association met at Atlanta, Ga., January 25 and 26, with Dr. H. L. Akridge, President, in the chair.

The following officers were elected for the year 1929: *President*—Gordon T. Crozier, M.D., Commissioner of Health, Valdosta; *Vice-President*—B. V. Elmore, M.D., Commissioner of Health, Rome; *Secretary-Treasurer*—Victor H. Bassett, M.D., City and County Health Officer, Savannah.

The association voted to make application for election as an Affiliated Society of the American Public Health Association.

NEW MEMBERS

Philip H. Bartholome, M.D., Lincoln, Neb., State Director of Public Health

Margaret Beattie, Berkeley, Calif., Assistant Professor of Public Health, University of California

L. D. Boone, M.D., Langley, S. C., Member Executive Committee, State Board of Health

Henry R. Buck, Ph.B., Hartford, Conn., Sanitary Engineer

John R. C. Carter, M.D., C.M., Harrisonburg, La., Director of Parish Health Unit

Walter B. Carter, LL.B., Washington, D. C., Statistician, U. S. Government

Francis E. Colien, B.S., M.S., Milwaukee, Wis., Bacteriologist, School Health Work, Director, Department of Bacteriology, Vocational School.

M. D. Cure, M.D., Weston, W. Va., County Health Officer

Walter W. Davis, A.B., Ph.D., Seattle, Wash., Supervisor of Hygiene in Public Schools

William Egleston, M.D., Hartsville, S. C., Member Executive Committee, State Board of Health

Davis Furman, M.D., Greenville, S. C., Member Executive Committee, State Board of Health

Lloyd R. Gates, B.S., Ann Arbor, Mich., Graduate Work in Public Health (Assoc.)

Clara E. Gilbertson, R.N., Wheeling, W. Va., City and County Tuberculosis Nurse

Lloyd M. Graves, Memphis, Tenn., City Health Officer

Schubert D. Henry, M.D., Kansas City, Kans., Director of Health

Charles Hunt, M.D., Clinton, Ky., County Health Officer

M. D. Ingram, M.D., Dresden, Tenn., County Health Officer

William A. Kelley, Ph.G., Philadelphia, Pa., Instructor of Chemistry, Temple University

Paul J. Lewis, B.Sc., Scottsbluff, Neb., Director of Branch Laboratory, State Department of Health

Dorothy Lottridge, M.D., East Orange, N. J., Medical Inspector of Schools

Charles B. Maits, B.S., M.D., Pittsburgh, Pa., Director of Health

George F. Manning, M.D., Flagstaff, Ariz., City and County Health Officer

C. H. Munger, M.D., Oskaloosa, Kans., Field Agent, U. S. Public Health Service

Arthur Noack, Hackensack, N. J., Consulting Municipal Engineer

William L. Orr, M.D., Louisa, Ky., Health Officer

Hal H. Puckett, Fayetteville, W. Va., County Health Officer

Anne Raymond, R.N., New York, N. Y., Field Representative, School Department, Cleanliness Institute

William R. Redden, New York, N. Y., Associate Health Director, Cleanliness Institute

Edgar T. Riley, M.D., Frenchburg, Ky., Health Director of Menifee County

Murrell O. Robinson, V.M.D., Philadelphia, Pa., Director of Laboratories, Scott-Powell Dairies

F. M. Routh, M.D., Columbia, S. C., Member of the Executive Committee of the State Board of Health

John Schreiber, M.D., Vidalia, La., Director Concordia County Parish Health Unit

Joseph E. Smith, M.D., Windsor, N. C., Health Officer of Bertie County

W. R. Wallace, M.D., Chester, S. C., Member Executive Committee, State Board of Health

Paul A. Watson, B.S., Pasadena, Calif. (Assoc.)

W. H. Wheeler, M.D., West Liberty, Ky., Director of Morgan County Health Department.

Maysil M. Williams, M.D., Bismarck, N. D., Director, Division of Child Hygiene, State Department of Health

Alice H. Wilmarth, B.S., Ellensburg, Wash., Director of Health Education, Washington State Normal School

Robert Wilson, Jr., M.D., Charleston, S. C., Chairman, Executive Committee, State Board of Health

Charles L. Woolley, Glen Rock, N. J., Executive Secretary, N. J. Public Health and Sanitary Association

DECEASED MEMBERS

C. B. Ball, Chicago, Ill. Elected member 1910—Fellow 1922

Alonzo B. Foster, M.D., Fonda, N. Y. Elected member 1926

John L. Gray, M.D., Caldwell, O. Elected member 1927

B. F. Lowry, M.D., Cleveland, O. Elected member 1920

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Spread of Scarlet Fever—A study has been made of the relation of carriers of hemolytic streptococci to family infection of scarlet fever. Throat cultures and Dick tests were made on every member of the household in which scarlet fever occurred. It was observed that in case the source of infection of the first patient could definitely be proved not to have been outside the home, some member of the household was found to carry abundant hemolytic streptococci of Beta type in the throat.

Throat cultures were made and the presence of hemolytic streptococci was expressed as follows: (+++) incalculable number of colonies; (++) more than 50 colonies; (+) less than 50 colonies; (—) no colony.

It was found that in 11 households with scarlet fever there were carriers of hemolytic streptococci. A brief outline of the carrier situation in each household is given. In one instance a 4-year old boy was diagnosed as having scarlet fever, and swab culture indicated (+++) hemolytic streptococci. A 9-year old brother also showed a (+++) hemolytic streptococci and a negative Dick test. The latter had complained of sore throat without rash for 4 days prior to the occurrence of the definitely diagnosed case of scarlet fever. Three cases of scarlet fever later developed among the younger brothers of the household and 5 cases occurred within a week among the classmates of the carrier and 6 cases among the neighbors who frequented the same public bath house.

A study was also made between the prevalence of positive cultures among convalescents and the incidence of "return" cases, from which it is concluded that convalescents may give rise to "return" cases, if they have relatively abundant hemolytic streptococci when discharged. Convalescents free from streptococci on discharge never give rise to "return" cases.—George Moriwaki, The Relationship of Hemolytic Streptococci to the Spread of Scarlet Fever, *J. Prev. Med.*, 3: 1 (Jan.), 1929.

Tuberculosis Prevention in Chicago—An enactment of the State Legislature in Illinois gives residents of cities and villages the right to determine by referendum vote the proposition as to whether they will levy a special tax to be used in the prevention and treatment of tuberculosis. At the present time the tax rate for this purpose in Chicago is 1.2 mills on each dollar of property, netting an annual revenue of over $2,000,000. This money is used for the support of the Chicago Municipal Tuberculosis Sanitarium and the clinics and field service maintained throughout the city, there being 8 dispensaries located in the congested districts of the city. In addition to these dispensaries there are a number of sub-stations which operate one-half day each week.

Each dispensary is managed by a head physician with the assistance of a head nurse. There are also part-time and full-time assistant physicians, public health nurses, a dentist, a dental hygienist, a stenographer, a clerk and a matron.

This bulletin contains a complete description of the procedure followed in the maintenance of these clinics and in-

cludes illustrations of the forms which are used and some good photographs. There are also organizational diagrams and maps of the city showing the geographical distribution of cases of tuberculosis.—*Bull. Chicago Municipal Tuberculosis Sanitarium,* Sept.–Dec., 1928.

Tuberculosis in Illinois—In 1927 the tuberculosis death rate (all forms) in Illinois was 74.8 per 100,000 population, which is just half the rate of 1880. The highest mortality is found in the southern part of the state in the district known as "Egypt." The report not only gives the tuberculosis death rate by sex and age but also by counties from 1918 to 1928 inclusive. Contrasted with such maps is one which portrays the annual per capita expenditure for public tuberculosis work, from which it is seen that the expenditures are higher in the northern part of the state where the death rate is lower.

Sanatoriums and clinics are needed in the future tuberculosis program as likewise more attention to the pasteurization of milk and the organization of tuberculosis units coupled with additional publicity and education. The program for the eradication of tuberculosis in animals is progressing and the number of accredited counties is increasing annually.—*Ill. Health Quart.,* Jan.–Mar., 1928.

Survey of Public Health Activities in Montreal—Under the guidance of the Montreal Anti-tuberculosis and General Health League, a survey of the community health activities in Montreal has been completed. The Committee on Administrative Practice of the American Public Health Association was engaged in a consultant capacity, and the report has been printed by the Metropolitan Life Insurance Company.

Based upon the *Appraisal Form* (2d ed.) Montreal scores 624 points out of a possible 1,000. The survey follows the general outline of the *Appraisal Form* and concrete recommendations are made for each division of service.

The major recommendations, however, suggest the appointment of a board of health; provision for an adequate budget for the health department, to make possible a proper school health service, laboratory service, communicable disease control and other essential services. The continued coöperation of the voluntary health organizations is to be encouraged.

In 1927 Montreal spent 39 cents per capita for its Municipal Health Department. It is recommended that this expenditure be increased to 91 cents per capita in order to make possible the establishment of those services which are considered essential to the maintenance of a modern health department.—Survey Public Health Activities of Montreal, Oct., 1928. (Available through American Public Health Association.)

State vs. Municipal Control of Milk Supplies—In both Canada and the United States, the control of milk supplies is in the hands of the municipalities. Such control may be satisfactory in the larger cities where health education is advanced sufficiently to induce the public to demand the best article. Outside the larger cities, in the towns and villages, municipal control of milk supplies is a failure. A great deal of education and moral suasion are expended by health departments in the endeavor to have the local authorities enact the by-laws necessary and, that done, to have these by-laws enforced. The consequence is that the local milk supplies in the smaller places are anything but satisfactory.

As a rule there is more or less state or provincial control of water supplies, with the result that, in most places, the water is safe for use. There is supervision by officers of the state or pro-

vincial health authorities and the presence of contaminated water in a municipality is at once checked up and corrected.

Why not a similar control of milk supplies? The writer has consistently advocated this reform for some years, with, he regrets to say, little result. It has the backing of Ontario Milk producers and of all who are conversant with the present situation in regard to milk production and distribution. Education of the public in health, while slow, is a powerful factor in the improvement of milk supplies. Education of legislators is quite as necessary and important.—John W. S. McCullough, M.D.

ANNUAL REPORTS AT A REASONABLE COST

W. W. BAUER, M. D., FELLOW A. P. H. A.

Commissioner of Health, Racine, Wis.

ANNUAL reports are a necessity from the administrative and educational standpoints for every health department. At the same time the cost of printing is high, especially where tabular matter, charts and illustrations are necessary, and without these no annual report is satisfactory.

The Racine Health Department in 1924 tried the experiment of combining printing and mimeograph reproduction for the publication of the annual report. The cover is printed and the binding of the report is done professionally. The remainder, except for illustrations and charts, is reproduced in the office of the health department on the mimeograph. The charts are reproduced either by the blueprint or black-line process. They are first drawn on draftsman's vellum paper, and the legends and figures entered on the typewriter using pencil carbon with the black side toward the chart, thus impressing the letters and figures on both sides of the paper to insure sufficient opaqueness for a clear blueprint or black-line negative.

The necessary equipment is nothing more than a typewriter and a mimeograph with slip-sheeting device. Typewriter type must be cleaned frequently with a copper wire brush to keep the impressions sharp. Stencils must be fresh stock. Ink pads on the duplicator must frequently be changed.

In addition to the costs for material and service, which are tabulated below, the 1928 annual report of the health department required the equivalent of 8 days uninterrupted time of one operator in cutting 63 stencils and 3 days uninterrupted time of one operator for running 125 copies of each. The time involved in preparing the data has not been estimated because it is part of the administrative duty of the department and represents work which should be performed whether a report is published or not.

In many instances material which has been used for other purposes can form a part of the annual report if its use for that purpose is kept in mind throughout the year. For example, in preparing circular letter enclosures, it is frequently possible to design them of such size and arrangement as will make them available for inclusion in the annual report, thus making the cost for the latter purpose practically negligible, since 100 or so additional copies of material already on the press cost very little.

Taking for example the 1928 annual report, the cost of which ran slightly higher than the table of estimates shown in that report itself, because of unfore-

seen wastage and added length, we get the following figures:

Grade A white bond paper, 16 reams @ $1.60	$25.60
Cover-stock, printing and binding	29.75
Folded page of illustrations *	3.00
Two pages black-line charts	15.00
Stencils, 2¾ quires @ $3.25	8.95
	$82.30

The prompt availability of annual reports is of the utmost importance. It is much easier to compile the wanted data monthly and then simply to add up a few figures at the end of the year than to let it all accumulate to be done at one time. We prepare in January each year a set of folders in which data for our various activities are compiled at the end of each month. Thus we have one folder for educational activities, one for nursing, one for vital statistics, one for milk inspection, one for meat inspection, one for the garbage division, one for the hospital, one for sanitary inspection, one for infant death study and special folders for the annual diphtheria prevention and smallpox vaccination campaigns. There is also a special folder for entering the public addresses and lectures given by members of the staff, in which we keep the date, the topic, the name of the group addressed and the number of persons reached. This gives us the data for our annual appraisal complete by January 10 without undue pressure on the organization. The only appraisal data for which we sometimes have to wait are those which come from outside the health department. Even for these we have induced the American Red Cross to keep monthly folders prepared by us for the infant and preschool work which they perform and we keep a list of necessary data from without the department so that we may write letters requesting this material about December 20 each year.

* Engravings for these pages were loaned by *The Survey*, New York, after publication of this material in their magazine.

Captain Cook and Scurvy[1]

THE credit for the discovery of the prevention of scurvy which is generally given to Captain Cook appears to be due to a physician, Dr. MacBride. Captain Cook deserves the highest commendation for his intelligent practical application of the suggested methods.

The "Endeavour" left Plymouth on 26th August, 1768. Twenty-seven days previous thereto the Lord of the Admiralty wrote to Lieut. Cook: "Whereas there is great reason to believe from what Dr. MacBride has recommended in his book entitled 'Experimental Essays on the Scurvy and other Subjects,' and his pamphlets entitled 'An Historical Account of the New Method of Treating the Scurvy at Sea' (of which you will herewith receive copies), and from the opinion of other persons acquainted with scorbutic and other putrid diseases: and whereas we think fit experiments should be made of the good effects of it in your present intended voyage, and have with that view directed the Commissioners of the Victualling to put a quantity on board barque you command. . . . " There follow directions for the making of the infusion of wort and the prescription of a quart a day. The surgeon is to keep an exact journal of the effects of the wort in scorbutic and other putrid diseases . . . noting down . . . the cases in which it is given, describing the several symptoms and relating the progress and effects from time to time, "which journal is to be transmitted to us at the end of the voyage."[2]

LABORATORY

C. C. YOUNG

A PRESUMPTIVE TEST FOR TULAREMIA

THOMAS G. HULL, PH. D., FELLOW A. P. H. A.

Chief Bacteriologist, Illinois Department of Public Health, Springfield, Ill.

THE following directions are given by Francis of the U. S. Public Health Service for making tularemia antigen. These have been available in mimeographed form but have not been published otherwise, hence are given below. The organism used is *Bacterium tularense* No. 38, which was isolated by Francis from a human case in Utah in 1920. Since August, 1921, it has been grown exclusively on artificial culture media and is now non-virulent for guinea pigs and rabbits.

CULTURE MEDIUM FOR BACTERIUM TULARENSE

Blood glucose cystine agar

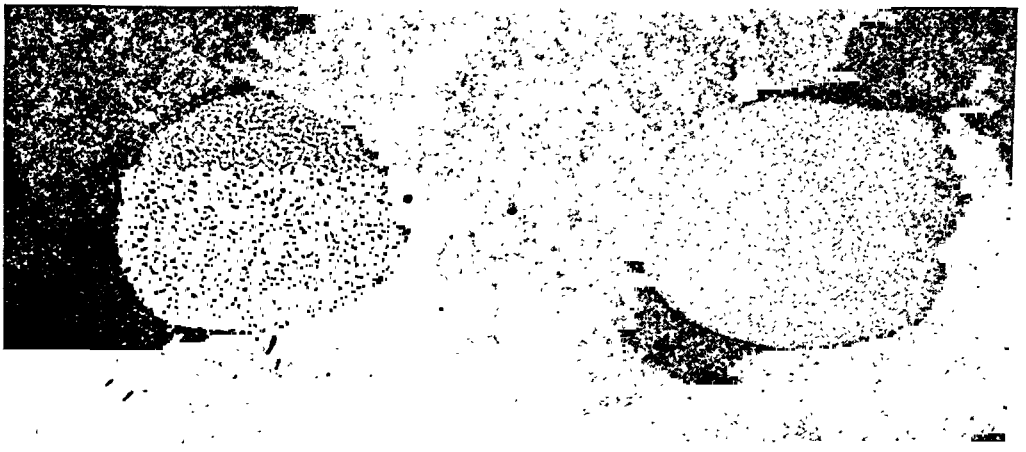
Fresh beef infusion agar, containing 1.0 per cent peptone, 1.5 per cent agar, and 0.5 per cent sodium chloride, adjusted to a pH of 7.3 is kept on hand in stock. When needed, there is added to the stock agar 0.5 per cent of cystine and 1.0 per cent glucose, and this is heated in an Arnold steam sterilizer sufficiently long to melt the agar and to sterilize the cystine and glucose, after which it is cooled to 40 to 45° C., when 5 to 8 per cent defibrinated rabbit blood is added. Overheating and loss of the bright red color should be avoided. The medium is then tubed, slanted and incubated to insure sterility.

The addition of cystine does not change the pH of the medium, but if cystine hydrochloride is substituted for cystine, a correction may be necessary on account of acidity. Cystine is not very soluble in the beef infusion peptone agar, and for that reason it should be pulverized before being added; even then, visible particles settle in the medium.

Tubes in which the water or condensation has evaporated are preferable. The organism scarcely grows in a liquid medium. Freshly prepared tubes with moist surface and with abundant water of condensation should be allowed to stand with cotton stoppers, in a slanted position, in the incubator at 37° C. for about 1 week, until almost free of water of condensation. They are then stood upright and plugged with cork stoppers soaked in a very hot mixture of 1 part vaseline and 2 parts paraffine, to prevent further evaporation; then they are stored in the cold room.

Stock cultures are kept in the cold room and transferred every 2 months. Cultures are stoppered with cotton during 2 or 3 days of incubation but with paraffine cork during 2 months in the cold room at 5 to 10° C., preferably 5° C.

A large loopful of growth is carried over when making transfers. A control tube of plain agar should show no growth.



The blood in the medium conduces to luxuriance of growth and to longevity of life of the culture; 8 per cent is preferable to 5 per cent. Human blood might be more accessible than rabbit blood and might serve equally well.

MAKING THE ANTIGEN FOR AGGLUTINATION TESTS

Blood is omitted from the medium when growing antigens for agglutination or absorption tests. The medium then becomes glucose cystine agar.

Blake bottles containing glucose cystine agar are employed when a large quantity of antigen is desired. Before being inoculated the bottles should dry several days in an inverted position in the incubator, and any water of condensation should be pipetted off before inoculation. Each bottle is inoculated with the entire growth from a blood glucose cystine agar slant suspended in 1 c.c. of physiological saline solution. This suspension is quickly spread over the surface of the medium in the Blake bottle by rocking the bottle in the hands, all excess of fluid being absorbed by the dry medium.

Incubate the bottles in their normal non-

Positive *Negative*

SLIDE AGGLUTINATION TESTS FOR TULAREMIA

inverted position at 37° C. for 3 days. Take off the growth of each bottle in 15 c.c. of physiological saline solution containing 0.2 or 0.3 per cent of formalin (U. S. P. strength, 37 per cent). Throw down the bacterial mass in the centrifuge, thereby washing the organisms. Pour off the fluid. Take up the bacterial mass in saline containing 0.2 or 0.3 per cent formalin. This concentrated stock suspension has been found to be entirely reliable for agglutination tests even after storage for 2 years in the cold room. Portions of the concentrated suspension are diluted at the time of use with saline solution to the desired turbidity, using any method of determining the turbidity, the simplest, cheapest and most practical of which is the silica standard.

THE PRESUMPTIVE TEST

One drop of concentrated antigen is mixed on a glass slide with one drop of serum, either diluted or undiluted. Within 30 to 60 seconds the reaction is usually complete, as easily determined when the slide is tilted back and forth against the light. This method does not give reactions in as high dilutions as the slow test in tubes because the material dries up too soon. Protected from drying by a vaseline ring and cover glass, however, the results are almost identical by the two methods. Dried blood submitted on foil may be moistened with distilled water and tested with very satisfactory results.

The accuracy of the test is high. In no case has it been known to give false positives. In one instance it gave a negative reaction in a very weak serum (1:15 highest titer by slow method). In another instance it gave a positive reaction in an undiluted weak serum that was missed by the slow method because the lowest dilution was 1:20. All specimens are tested with abortus antigen for undulant fever by the Huddleson slide agglutination method. Occasionally cross agglutinations are encountered, but when these have been worked out they have always been, in our experience, cases of tularemia instead of undulant fever.

The presumptive test is followed by the slow test for purposes of confirmation, using 0.3 c.c. of various dilutions of serum with 0.3 c.c. of diluted antigen. Incubation in the water bath at 37° C. for 2 hours is usually sufficient but subsequent standing overnight in the icebox makes the reactions more clear-cut.

STANDARDIZATION OF LABORATORY RECORDS AND APPRAISAL VALUES *

THIS committee appointed at the 1927 annual meeting of the Association was requested to offer suggestions to the Sub-Committee on the Revision of Appraisal Form for City Health Work of the Committee on Administrative Practice before the new edition of the *Appraisal Form for City Health Work* was printed.

Your committee held three meetings and carried on a lengthy correspondence. Although failing to cover the entire field for which they were appointed they have concentrated on the subject of municipal laboratory appraisal values, making suggestions that have led to changes, which they believe improvements, in the Third Edition (1929) of the *Appraisal Form.*† Some changes are embodied in the form itself while others are in the nature of clarifying footnotes. Important changes may be listed as follows:

1. A definition of a "specimen" was made and credit based on the number of actual specimens submitted.

2. A method was devised whereby credit could be obtained for "additional reportable results" on specimens subjected to more than one examination.

3. The standards for diphtheria, typhoid and tuberculosis were changed from the basis of "annual deaths" to the basis of "annual resident deaths" and adjusted to conform to past experience of a selected group of cities.

4. The standards for gonorrhea and syphilis were changed from the basis of cases reported to a population basis.

5. The standard for milk was changed from a basic standard for all classes of milk to specific standards for the following classes:

a. Certified and other raw milk
b. Pasteurized milk
c. Raw milk previous to pasteurization

6. Standards for water examination were similarly changed from a basic standard for all waters into specific standards for public supplies and for semi-public supplies, such as private springs and wells, swimming pools and bathing beaches.

7. Amplification of the miscellaneous group was made to permit scoring of activities not mentioned in previous score forms.

8. Tentative standards were set up for the new item of laboratory reportable results.

9. It was provided that in states having approved laboratories, credit should be taken only for such approved services.

COMMITTEE SUGGESTIONS ON THE USE OF THE PRINTED FORM, THIRD EDITION

Section f. i. should include other raw milk sold in the city as well as certified milk.

In the note under Section f. iii., raw milk previous to pasteurization, alternative credit should be allowed for the direct microscopic count (Breed method). In scoring it should be clear that credit for total laboratory procedure, item h., should be based on the total of the three items, total specimens, other specimens, and additional reportable results, and therefore should be the sum of the figures in the first three columns.

It was the opinion of the committee

* Report of the Committee to the Laboratory Section of the A. P. H. A.

† American Public Health Association, 370 Seventh Avenue, New York, N. Y.

that credit should be taken in the third column for each "reportable" result, even though the result was not definitely "reported" to the person submitting the specimen.

RECOMMENDATIONS

1. Some method was considered of crediting the other communicable disease laboratory services: Bacillary dysentery, Intestinal parasites, Malaria, Meningitis, Plague, Pneumonia, Rabies, Tularemia, Typhus fever and Undulant fever, but the information at hand was insufficient for the setting up of tentative standards. The committee hopes that future experience will permit setting up of separate standards for at least some, if not all, of these diseases before the next revision of the *Appraisal Form for City Health Work.*

2. The committee feels that possibly more attention should in the future be paid to the scope of service offered in various laboratories instead of basing entire credit on volume alone.

3. The committee feels the problem has only been touched and recommends to the Laboratory Section that further studies are necessary in the light both of the foregoing recommendations and of the results obtained through the application of the newly revised *Appraisal Form.* Further studies should also be made of such internal laboratory changes as are necessary to arrive at uniform methods of keeping records and reporting the volume of work done, including the devising of suitable forms for this through which future scoring and comparison of laboratories can be placed on a more uniform basis.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

The Diabetes Record for 1927—The use of insulin since 1923 does not seem to have arrested the rising death rate from diabetes. The United States, with an average death rate of 17.3 per 100,000 population for the period 1921–1925, had the highest rate among 15 representative civilized countries. Holland had a rate of 14.1 per 100,000 population, England and Wales 11.3, Italy 5.5 and Chile a rate of 2.9. In 1916 the United States had a diabetes mortality rate of 17.1 per 100,000, as compared with 12.9 for England and Wales. The rate for the United States reached a minimum of 14.9 in 1919, but subsequent to this date the rate increased to a maximum of 18.4 in 1922. It then declined to 16.6 in 1924, increasing to 16.9 in 1925 and 18.0 in 1926. The diabetes mortality rate in England and Wales has followed a somewhat similar course. It reached a minimum of 10.0 in 1920, increased to 11.9 in 1922, decreased to 10.9 in 1924, and then rose again to 11.5 in 1926.

Between 1912 and 1921 the diabetes death rate in 37 cities of the United States increased from 15.7 per 100,000 population to 18.1. In 1927 the average rate for these cities was 20.5. In a study of 22 cities of the United States during 1927 the diabetes death rates ranged from a maximum of 35.2 per 100,000 population in Concord, N. H., and 34.7 in Pawtucket, R. I., to a minimum of 4.1 in Chester, Pa., and 3.1 in Wichita, Kan.

A comprehensive study of diabetes mortality suggests a reëxamination of the original death certificates of representative areas for at least a period of 5 years. The early treatment of diabetes would be improved if accurate observations were available regarding individual weight curves from youth to middle life.—Frederick L. Hoffman, *Spectator,* 122: 27–29 (Jan. 17), 1929.

The Relative Position of Diabetes as a Cause of Death—In 1902 there were 47,491 deaths from all causes in Massachusetts. According to the International Classification of Causes of Death, diabetes with 379 deaths ranked number 21 in frequency. For the year 1910, the disease ranked 18th. There were 575 deaths, and they constituted 1.1 per cent of the deaths from all causes. In 1920 diabetes with 796 deaths was ranked number 13 on the list, and constituted 1.5 per cent of the deaths from all causes. In 1925 and 1927 diabetes ranked number 11. In 1927 there were 844 deaths from diabetes, constituting 1.7 per cent of deaths from all causes.—A. Hamblen and E. Joslin, *New England J. Med.,* Nov. 8, 1928.

Diabetic Children—In the 22 months ending July 1, 1928, there was a mortality of 2 per cent among 303 diabetic children. Thirteen living patients and 3 who died had diabetes for 10 years or longer. The average duration of the disease in 195 living patients seen prior to September 1, 1926, was 5.8 years. A diabetic heredity of 17 per cent was found in a group of 201 fatal cases, as contrasted with a heredity of 31.8 per cent found among 201 living children. Fifteen per cent of 256 children were 11 pounds or more underweight, and 2 per cent were more than 20 pounds underweight. Overheight at the onset of diabetes was on the average 2.7 inches for 100 children. Cataemia was established or continued in 93 per cent of 27 girls. No cataracts were recognized in 297 living diabetic children. Arteriosclerosis was demonstrated by the roentgen ray in 5 of 29 children. The cholesterol value among 67 per cent of 75 children was below the normal for such patients. Tubercle bacilli were found in the sputum of 1 patient among 17 examined. Evident pulmonary tuberculosis was present in 2 cases, and the chest conditions were suggestive in 16 cases. Insulin reactions were distressing but almost never fatal. Diabetic children withstood all types of infection by proper adjustment of diet and insulin.—E. P. Joslin and P. White, *J. A. M. A.,* 92: 143–146 (Jan. 12), 1929.

Diabetes Mellitus in the Negro—Since the beginning of the colored hospital of Atlanta, Ga., in 1921, of 26,858 admissions to all services, 113 have been for diabetes, giving an incidence of 4.2 per 1,000 admissions. In a series of 71 cases, 8 of the males showed an onset of diabetic symptoms between the ages of 30 and 39, whereas 11 of the female cases in the group showed symptoms during this period. Between the ages of 40 and 49, 7 males in the series and 15 females began to show symptoms, and between the ages of 50 and 59, 2 of the male cases and 12 of the female first showed symptoms. After the second decade of age, diabetes among negroes seems to appear about 10 years earlier than in the white race. In 32 cases symptoms of diabetes had been present for more than 2 years. The greatest duration was 17 years in an obese colored physician. Thirteen of the patients with diabetes of long duration experienced the onset of symptoms during the fifth decade.

Seventy cases of the series of 100 were female. This comparatively high incidence among females may be due to their marked obesity, which is one of

the most important single factors influencing the development of diabetes among negroes. Of 34 clinic cases, 76.5 per cent (3 males and 23 females) had a weight of more than 10 per cent in excess of the average standards for white individuals of the same height and age. Syphilis did not seem to be an important etiological factor. The incidence of positive Wassermann tests was 14.1 per cent. Clinical arteriosclerosis was present in 43 or 55.1 per cent of 78 patients. Among 81 patients, 36 or 44.4 per cent showed evidence of hypertension. Extensive active tuberculosis was present in 2 cases. Among 36 clinic cases, 20 received from 10 to 60 units of insulin daily. There were 25 hospital admissions of patients in a state of impending or deep coma; 14 of these patients recovered and 11 died. There were 2 deaths, 1 from tuberculosis and the other from an accident, among the 36 clinic cases. Among the hospital admissions, there were 27 deaths.

Diabetes is usually mild among the negroes, and the greatest handicap to adequate control of the disease is poor coöperation due to poverty and lack of intelligence. The same complications appear in the negro and white diabetic. Successful results in control of the disease can be obtained in the colored patient, after instruction in the general principles of diet, insulin dosage, administration of insulin and the technic of testing urine in sugar.—Harold M. Bowcock, *South. M. J.*, 21: 994–999 (Dec.), 1928.

Vital Statistics of the Irish Free State for 1927—The Registrar-General of the Irish Free State reports that there was a death rate from all causes of 14.8 per 1,000 population for 1927. This is lower than the average rate of 15.4 for the previous 10 years, but higher than the rate of 14.1 for 1926. The birth rate for the year was 20.3 per 1,000 population, being 0.05 below the average for the previous 10 years. The birth rate in Northern Ireland was 21.3, in England and Wales 16.6, and in Scotland 19.8. Infants under 1 year of age showed a mortality rate of 71 per 1,000 births, as compared with 74 per 1,000 in 1926. In Northern Ireland the rate was 78, in England and Wales 70, and in Scotland 89. The low rate in the Irish Free State is due to the low mortality in rural areas. In the city of Dublin the infant mortality rate for 1927 was 123 per 1,000 births. The increase in the general death rate was due chiefly to influenza, heart disease and respiratory diseases. The death rate from tuberculosis was the lowest on record, being 1.45 per 1,000 population. The corresponding rate in Northern Ireland was 1.41, in England and Wales 0.97, and in Scotland 1.0. Heart disease was responsible for 5,031 deaths, 375 more than for 1926. The deaths from cancer continued to increase, the total number, 3,113, being the highest on record.—Report of the Registrar-General of the Irish Free State, *Lancet*, 2: 1315 (Dec. 22), 1928.

Puerperal Septicemia in Massachusetts in 1927—A study of the 140 deaths from puerperal septicemia in Massachusetts during 1927 was made by a committee appointed by the Section of Gynecology and Obstetrics of the Massachusetts Medical Society. Questionnaires were sent to all physicians who had reported a case of puerperal sepsis during 1927, and 94 responses were received. In a group of 50 cases studied, 52 per cent of the fatal cases were delivered at home, as against 48 per cent delivered in hospitals. Forty-four per cent of the 50 cases who had operative procedure were fatal, as compared with a fatality of 46 per cent among patients with normal deliveries. Toxemia of pregnancy was evident in 10 per cent of the cases. Thirty-four per cent of the 50 cases stated there had

been antepartum care. In 24 per cent of the 50 cases, the first symptoms of puerperal sepsis appeared on the third day after delivery. Thirty-eight per cent of the cases had perineal tears, 30 per cent did not, and no information was received about the remaining cases.

There were 20 cases of incomplete abortion reported among the 94 cases. Two of these gave evidence of artificial interference with pregnancy. One case aborted after an operation for diverticulitis, and septicemia developed. Two others were cases of appendicitis associated with pregnancy. The remaining 15 cases aborted outside of hospitals, and called medical service only when they were extremely ill. These patients stayed in the hospital on an average of 6 days. There were 5 deaths from puerperal sepsis associated with cesarean section and 2 from ruptured uteri followed by sepsis.

There appears to be a definite seasonal variation of the disease. In New York State in 1914–1920 it was found that the greatest number of cases was in the month of March. In Massachusetts during 1927, May was the month of highest incidence. A considerable number of cases are infected where no examination, either internal or external, has been made. These deaths should not be charged to laxity on the part of the profession.—Report of the Committee on Survey of Incidence of Puerperal Septicemia in Massachusetts in 1927, *New England J. Med.*, 199: 25, 1253–1259 (Dec. 20), 1928.

Lengthened Life of the German Population—The mortality statistics as set forth in the new German mortuary tables for the years 1924 to 1926 may be regarded as comparatively favorable. The infant mortality rate has decreased about 44 per cent since the beginning of the 20th century. The infant mortality rates for the years 1924 to 1926 were 115.4 for males and 93.9 for females per 1,000 live births, as compared with 202.3 and 170.5, respectively, for the period 1901 to 1910. There was also a great decline in the mortality among children aged 1 to 5 years. Of 1,000 children 16.2 boys and 14.9 girls died in the second year of life, or only two-fifths as many as 20 years ago. The decrease in the mortality rates for the age groups 15 to 25 has been less marked. The mortality of 4.3 per 1,000 population among 20-year old males, and 3.3 among 20-year old females, was only about 15 and 21 per cent lower, respectively, than the average for the decade 1901 to 1910. In the next higher age groups the mortality especially among men has undergone a much greater reduction. Of 1,000 men aged 30, only 4.1 died, as compared with 5.6, the average mortality for the decade 1901 to 1910. The mortality of men aged 35 and 40 was 4.3 and 5.4 per 1,000 respectively, as compared with 7.0 and 9.2, respectively, for the decade 1901 to 1910. The reversal of mortality conditions observed in men in the 20- to 30-year age groups as against the 30- to 40-year groups has not been duplicated in women chiefly on account of the additional hazard of pregnancies. Above 50 improvement in the mortality rates becomes less with increasing age.

The marked diminution in the mortality of all age groups results in a lengthening of life of the population as a whole. The lengthening of life is most noticeable in the first 5 years of life. According to the mortality conditions of the period 1871 to 1880, the new-born males attained an average age of 35.6, and according to the conditions that prevailed during the decade 1901 to 1910, they attained an average age of 44.8. Under present conditions the average age of males is 56. During the past 50 years the life expectancy of new-born females has increased from 38.5 years to 58.8 years.—*J. A. M. A.*, 92: 576 (Feb. 16), 1929.

Tonsillectomy and Rheumatic Heart Disease—The records of 413 rheumatic children were investigated, and the children observed over a period ranging from 1 to 10 years. In 247 cases the tonsils were removed, and the remaining 166 cases served as controls. Of 245 children subjected to tonsillectomy, manifestations of rheumatic infection recurred in 47.7 per cent; and infection appeared for the first time in 34.7 per cent. There was no recurrence of infection in 17.5 per cent of the cases. In 22.8 per cent of the 245 cases the operation was performed at the age of 5 years or less. The first infection occurred in 62.5 per cent of these children after tonsillectomy. There was recurrence of infection in 30.4 per cent of these cases. The operation was performed between the ages of 6 and 9 in 47.4 per cent of the children. A recurrence of infection occurred among 50.9 per cent and the first infection occurred after tonsillectomy in 35.3 per cent of these children. Tonsillectomy was performed among 29.8 per cent of the cases at ages of 10 years and over. Of these 56.2 per cent had a recurrence of infection, while the first infection occurred after tonsillectomy in 12.2 per cent. Of the 247 children from whom the tonsils were removed, 50.2 per cent experienced recurrent tonsillitis, and 49.8 per cent experienced no recurrence. Of 166 children who were not operated upon, 48.2 per cent gave a history of recurrent tonsillitis, and 51.8 per cent gave a history of no recurrence.

The age at which tonsillectomy is performed seems to be the significant factor in the evidence of infection after the operation, but this study seems to indicate that the routine removal of tonsils for the prevention of rheumatic heart disease in children is not based on conclusive data.—M. Wilson, C. Lingg, and G. Croxford, Statistical Studies Bearing on Problems in the Classification of Heart Disease, *Am. Heart J.*, 4: 197–209 (Dec.), 1928.

Health in Uganda, Africa—A report on Uganda for 1927 was recently issued on the authority of the Colonial Office. The protectorate covers approximately 94,204 square miles. The population on December 31, 1927, was estimated to be 3,149,354. Of these, 1,867 were Europeans, 11,502 Asiatics, and 3,135,985 natives. The climate of the protectorate is not considered healthy for Europeans, and outdoor manual labor is dangerous for them.

The excess of births over deaths reported for five districts of the protectorate was 17,000. Syphilis, malaria, yaws, and ulcers are the four commonest diseases in the country. Pneumonia, dysentery, and injuries account for the largest number of deaths in hospitals. Plague and sleeping sickness required more attention than usual during the year. There are 4 government European, 9 Asiatic, 28 native, and 11 isolation hospitals in the protectorate. These provide beds for 27 Europeans, 51 Asiatics and 1,391 natives. In addition there are 97 beds in isolation hospitals which may be used for either Asiatics or natives. There were 480,514 new cases recorded as having attended the various government hospitals, dispensaries and medical centers. This is an increase of 100,117 cases over the number recorded in 1926. There were 1,111 deaths in hospitals for 1927, as compared with 1,397 in 1926. This was accounted for by the falling off in the number of cases of dysentery during the year. Grants are made by the government toward the cost of medical training of both native attendants and midwives at mission hospitals and maternity training schools.—*Lancet*, 2: 955–956 (Nov. 3), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Gas Production from Sewage Sludge—Sludge gas originates from the anaerobic decomposition of organic sewage solids. In this decomposition enzymes play an important part in accelerating the reactions involved. The gas consists mainly of methane, together with carbon dioxide and nitrogen and occasionally hydrogen, oxygen, carbon monoxide and hydrogen sulphide. Methane is formed by the decomposition of cellulose and the fermentation of alcohols. According to Söhngens it is also formed by direct reduction of carbon dioxide by hydrogen. Carbon dioxide is produced in the methane fermentation and in processes in which hydrogen is also formed.

The process of the formation of nitrogen is not clearly understood but it probably originates in the decomposition of albuminous substances. Hydrogen is produced in the process of fermentation of pectose, carbohydrates and albuminoids. It is in general not formed in the regular operation of digestion chambers since it reacts with the carbon dioxide. Hydrogen sulphide only occurs in badly operated tanks. The evolution of gas occurs between 6 and 50° C., the optimum temperature lying at 25° C. The pH should be between 7.0 and 7.6. The gas has usually the following composition: 70–80 per cent methane, 15–30 per cent carbon dioxide, 0–8 per cent nitrogen, and has a heating value of 780–900 B.t.u. per cu. ft. Separate digestion chambers are in general not suitable. The evolution of gas is increased if the digesting solids are agitated. Two story tanks are very suitable since the surface of the digestion portion is small, and the solids are kept comparatively warm by the incoming sewage. A good mixing of ripe and fresh solids is also obtained in these tanks. With separate digestion, artificial heating and mixing are usually necessary. In Germany sludge gas is used for heating and power supply, and is frequently mixed with municipal coal gas for lighting purposes.—Heilmann. Paper read before a meeting of the Verein deutscher Chemiker. *Chem.-Ztg.*, 52, 482, 1928. (From papers of Water Pollution Research Board, England.)

Municipal Work in Wakefield—A description is given of the two sewage disposal works of Wakefield at Calder Vale and Agbrigg. Both of these works are now using the activated sludge process, aeration being effected by Haworth's paddle method. The Calder Vale plant, which serves a population of 46,626 and has an average d.w.f. of 2,327,000 gal. containing 53 per cent of industrial wastes, is designed to give full treatment to 3 times the d.w.f. and storm water treatment to any excess up to 5 times d.w.f. The trade wastes consist of wool scourings and textile wastes, salts of iron, dye waste and malting refuse. The plant consists of screens, grit tanks (96,000 gal.), preliminary settling tanks (1,008,500 gal.), fine screens, 4 aeration tanks (2,000,000 gal.) and final settling tanks of the Dortmund type (820,800 gal.). The amount of returned sludge is 8–10 per cent of the volume of incoming sewage. The excess storm water will pass into a storm water tank (340,000 gal.) and will be dosed on to an old percolating filter. The Agbrigg works has been de-

signed to treat a d.w.f. of 267,000 gal. from a population of 13,350. Three times the d.w.f. will be given full treatment. The sewage is of a strong domestic type and contains little trade waste. The plant consists of coarse screens, detritus tanks (33,500 gal.), fine screens, aeration tank (148,000 gal.) and settling tanks of the Dortmund type (80,000 gal.). The amount of returned sludge is 15–25 per cent of the volume of incoming sewage. The excess storm water is passed into a tank of 53,000 gal. capacity and dosed on to an old percolating filter.—L. Ives, *J. Inst. Mun. & County Eng.*, 54: 1577, 1928. (From papers of Water Pollution Research Board, England.)

Typhoid Fever and Its Occurrence in Honduras—In this article is reported an attempt to determine the source of typhoid fever which has occurred sporadically in Tegucigalpa and Comayaguela, Honduras, for the past few years.

Water for these municipalities is taken from a mountain stream which is impounded to provide storage. From here a pressure conduit supplies a reservoir close to the cities mentioned. Previous examination of the watershed disclosed possible contamination from flood washing of inhabited areas following heavy rains. An examination conducted by the health department this past year discounts this as a source of contamination, the dry, arid, vegetation-free surroundings insuring freedom from active contamination at this point.

The author expresses his conviction that lack of latrines and the excessive prevalence of flies close to town are the main causes of enteric infections in the cities. He stresses the necessity of: (1) Constructing fly tight latrines both in the cities and in the country, and (2) systematic destruction of flies.—Anon., *Bol. San. Honduras*, 7, 11: 1 (Aug.), 1928. Abstr. H. A. Johnson.

Experimental Studies of Bacterial Death Rates in Polluted Waters—In an attempt to understand better the processes of natural purification as observed in streams, the Stream Pollution Investigations Laboratory of the U. S. Public Health Service has devoted considerable study to comparing the bacterial changes which take place in waters under various laboratory conditions with the changes occurring in the stream. In these studies water collected from the Ohio River at Cincinnati was used. The bacterial changes occurring in the Ohio River between Cincinnati and Louisville have been determined.

The bacterial changes taking place with four experimental set-ups are given as follows: (1) Samples were stored in glass bottles in the incubator at temperatures of 10, 20 and 37° C.; (2) samples were held in wooden buckets at air temperatures, with intermittent agitation, and exposed to diffused daylight; (3) results are noted from samples stored suspended in the river at the site of collection; and (4) bacterial changes were followed in water pumped from the river and detoured through artificial channels constructed on the laboratory grounds.

Under the first three conditions the bacterial changes were not comparable with those observed in the stream. In the fourth set-up the changes observed simulate those in the natural stream.

The article is accompanied by tables of detailed analytical data and descriptive charts.—C. T. Butterfield, *J. Bact.*, 16, 4: 257–267 (Oct.), 1928. Abstr. C. T. Butterfield.

Attempts to Transmit Malaria Organisms Mechanically through Mosquito Biting—Noting the very short time required for the act of biting which produced natural infection from infected mosquitoes, the author made experiments to determine the possibility

of mechanical carriage of malaria by mosquitoes. Several species were used, one of aedes and one of anopheles. The mosquitoes were allowed to bite cases of malaria having numerous ringforms and moderate numbers of gametes in the blood, and then transferred to the non-infected subjects and allowed to engorge themselves completely. In this way the sexual phase of development in the mosquito was bridged over. In a series of twelve subjects exposed in this manner, no case of malaria occurred. Malaria organisms were found, however, in the mouthparts of mosquitoes examined immediately after biting a case of tertian malaria.—Bruce Mayne, *Indian J. M. Research,* 15, 4: 1067–1071 (Apr.), 1928. Abstr. W. H. W. Komp.

Liquor Effluents Research Committee—In a summary of the report by Dr. Parker, it is stated that the usual gas works practice of storing tar and liquor in the same well increases the effluent difficulty, since the ammoniacal liquor absorbs higher tar acids. Tar and liquor should be separated as soon as possible and stored separately. A tar extractor (designed by Woodall-Duckham) was installed at the Hinckley Gas Works, in the hot foul gas main of the retort house. This extractor reduced the quantity of higher tar acids in the mixture of the liquors condensed at various points, from the equivalent of approximately 240 parts of oxygen absorbed per 100,000 to 150 parts. Further improvements are anticipated. With regard to the oxygen content of the gas, it is clear that air for purification should be admitted at the inlet to the purifiers, after condensation and removal of liquor, if the quantities of thiocyanate and thiosulphate are to be kept at a minimum. The diminution in the temperature of the liquor in the tar and liquor well, consequent to the installation of the extractor, in addition to causing a smaller loss of ammonia, has resulted in less oxidation of the liquor. In consequence, a smaller removal of hydrocyanic acid in the Livesey washers and tower scrubbers has occurred and the amount of thiocyanate in the final liquor has fallen from an equivalent of 650 parts of oxygen absorbed per 100,000 to 410 parts and of thiosulphate from 160 to 80 parts. An improvement of 20 per cent in the oxygen absorbed value of the total effluent would be obtained if the " devil " liquor were treated separately by some such method as evaporation by spraying into the base of a hot chimney. Eighty-five per cent purification of effluent liquor can be obtained by biological filtration on two filters in series. Mixtures of spent liquor and bacterially purified effluent containing 8 per cent of the former should be used. Admixture of crude effluent with domestic sewage is permissible provided the flow is uniform. —2d Report, *Gas J.*, 182: 1016, 1928. (From papers of Water Pollution Research Board, England.)

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Some Aspects of Industrial Health Services—The author suggests a cooperative effort in which employer and employe may combine forces to mutual advantage, and points out a few health activities which establishments may undertake and which business executives have found to be profitable. The human machine is and will long remain the most vital and indispensable mechanism in the production of industrial wealth. The essential activities to be considered in organizing are: (a) medical services whose efforts are directed mainly toward disease prevention and health conservation, although curative measures should not be omitted, and general medical examinations, including those presumably well, should be stressed for a number of reasons (omitted by the abstractor); (b) first aid provisions conducted by thoroughly trained and experienced attendants, which have demonstrated their value in the marked reduction in the loss of time, and which are generally recognized as dividend paying investments of a high order; (c) a nursing service whose extent depends upon the policy relative to medical and surgical work, and the scope of outside agencies, the results of which may be measured in terms of lessened absenteeism and labor turnover, and increased loyalty, contentment, and efficiency; and (d) a dental service which has realized its importance in some 72 plants in the United States. (Names of some of these are given.)

In addition, an industrial health survey should be made of the plant with a detailed study of conditions which should be corrected. This will require no small degree of technical skill and business ability. The merits of industrial health work will depend to a large extent upon the objectives, and there are at least six principles which should be visioned: (1) It should be exactly as represented. (2) It should compose the spirit of service. (3) It should be developed as conditions warrant. (4) It should include preventive as well as curative measures. (5) It should take into consideration home and community conditions. (6) It should produce results which will fit the expenditures.

The costs of industrial health services will vary with a number of things, but will amount to from $6 to $12 per year per employe. Preventive dental work has ranged from $.47 per year to $3.03 per employe. These expenditures should be considered investments since they yield occasional dividends. One large concern in Canada reports a return of $1.26 on every $1 invested in its health program.

In summarizing the tangible returns from industrial health services, experience shows that returns can be measured in dollars and cents, in addition to any results which do not lend themselves to monetary calculations. An insurance company points out that periodic medical examinations have a potential life saving value of $30 each. The cost of labor turnover is estimated at $45 per person. Medical services should therefore be accredited with a minimum of $45 for each applicant examined who is found unfit for employment, and with a similar amount for applicants found fit for special employment only. Laboratory examinations should be con-

sidered worth the current local prices for same. First aid dressings and surgical operations have a tangible value according to local standards, while the installation of facilities in the plant effects a great time saving. The saving in infections and other serious complications may be conceivably placed at double the amount of operating expenditures. While the number of competent industrial health services is still relatively small, the tangible returns exceed the operating costs by a substantial majority.—Bernard L. Wyatt, Some Aspects of Industrial Health Services, Published by State Charities Aid Assn., New York, N. Y.

Recent Trends in Occupational Diseases in Ohio—Comparing reports of occupational diseases of the State Department of Health for the 2½-year period ending December 31, 1927, with the previous 5-year period ending June 30, 1925, the authors find that for the 15 compensable afflictions listed in the schedule of the Industrial Commission since 1921, the number of reports has increased rapidly from year to year; also reports of non-compensable occupational diseases have increased remarkably. The diagnosis of occupational diseases is made by any licensed practitioner of medicine, the employer is notified when the case is compensable and a hearing allowed in case of protest, while the State Department of Health and the Industrial Commission keep each other informed of all occupational disease reports received.

For the 2½-year period there was a total of 2,738 compensable cases, of which 2,400 were males and 338, females. The number of non-compensable cases reported was much smaller, consisting of 192 cases—170 males and 22 females. This makes a grand total of 2,930 reports. There were also approximately 182 cases reported which the authors could not classify as occupational diseases. Many of these were accidents, pure and simple, and some were diseases having no clear relation to occupation.

No cases of anthrax or glanders were reported during the period and these diseases have little importance in Ohio; in fact, no case of glanders has ever been reported in the records, which extend back to 1913. There were 450 cases of lead poisoning, the chief distributions being as follows: storage battery works, 121; painters, 106; automobile manufacturing, 39; brass and bronze products, 32; white lead plants, 28; the rest scattered through various occupations such as rubber workers, painters, pottery workers, enamellers, glass workers, chemical workers, etc. Two cases of mercury poisoning were reported, one in a metallurgist, and another in an art glass worker. No phosphorus poisoning was reported. Arsenic occurred in but 4 cases—a plate glass factory worker, a worker exposed to arsenureted hydrogen in a radiator factory, a sprayer of trees, and a milliner. There were 26 cases of benzol poisoning (including its derivatives). Eight cases from benzol occurred among sprayers in a novelty factory, 4 among rubber workers, 3 in dry cleaners, 1 in a shoe cementer, 1 in an oil station attendant, and 1 handling "Formica." Two para-toluidin poisonings occurred in dye makers. Nine cases of benzine and naphtha poisoning were reported in dry cleaners, pump testers, spray painters, and users of cleaning fluids. The 1 carbon bisulphide case occurred in rubber work. No wood alcohol poisoning was reported. Two cases of chronic mine gas poisoning are placed under carbon dioxide on the schedule. Brass and zinc poisoning furnished 11 and 17 cases respectively. Out of the total of 2,738 compensable cases, 2,210 were dermatoses, of which number 313 were in females (a long list of agents and exposures is given). The two largest

groups of dermatoses were 395 cases due to oils and cutting compounds, 608 cases associated with rubber manufacture, 104 due to lime and cement, and 149 due to acids and alkalies.

The 5 cases of epithelioma which were reported occurred upon the hands, cheeks, and lips from exposure to carbon, tar, and tarry compounds. But 1 case of compressed air illness occurred.

The non-compensable occupational diseases included a number of poisonings from carbon tetrachloride, cyanides, copper, "Duco," manganese, "rubber," and turpentine. Also a number of systemic diseases such as arthritis, asthma, bronchitis, pneumonia, tuberculosis, conjunctivitis, and diphtheria and scarlet fever (the two latter occurring in hospital employes). There were reported only 6 cases of silicosis and 6 of pneumonokoniosis, not including 261 reported by Kindel and Hayhurst in a special study of 919 sandstone quarrymen (this JOURNAL, August, 1927, pages 818–822).

The present yearly average of 1,172 reported cases is compared to the 645 average of the previous period, an increase of 81 per cent. Decreases were noted in but three limited groups—lead poisoning among automobile painters, benzol poisoning, and dermatitis among rubber workers. All others showed increases, some very great. The total increase in the compensable cases was 71 per cent, and in the non-compensable cases, 997 per cent. The authors have prepared tables presenting the relations to compensability, cause, industry, trade processes and sex, which are available for free distribution.

The increase in reported occupational diseases in Ohio is due, it is thought, not so much to an actual increase in the number of cases but to the increasing spread of information concerning them and the influence of the compensation law. Most of the more important afflictions have been investigated and means found to alleviate their effects, with a result that the afflictions are being reduced, particularly in severity. Oftentimes physicians have to be written to for additional information concerning the cases they have reported and occasionally the department finds it necessary to make a local investigation in order to satisfy itself. It is regretted that there is any arbitrary discrimination in the matter of compensating occupational diseases (as by the present schedule method), and would urge that all specific occupational diseases be made compensable in Ohio. Until that time comes experience will have to be built upon the faithfulness of physicians in reporting every non-compensable case, even though there is no opportunity for the medical fee to be derived from the state as in the case of the compensable cases.—Byron E. Neiswander and Emery R. Hayhurst, *Ohio State M. J.*, XXV, 1: 37–41 (Jan.), 1929.

The Summer Comfort Zone; Climate and Clothing—The present study describes an investigation in which the comfort zone for summer conditions was determined.

The studies were conducted in the psychrometric chamber at the Harvard School of Public Health. In all, 15 experiments were conducted, 8 of which were with progressively increasing room temperatures and 7 with decreasing room temperatures, in order to approach the comfort zone from the lower as well as the higher temperature condition.

The sensation of comfort was represented as before under 5 classes: cold, comfortably cold, very comfortable, comfortably warm, and too warm. In all there were 91 subjects, 56 males and 35 females.

All of the requisite observations of temperature, humidity and air motion were made and the effective temperatures were computed on the basis of

these observations. It was found from these studies that the probable lower limit of the comfort zone was at an effective temperature of 64° F., the probable optimum condition at 70.5° effective temperature, and the probable warm limit 79° effective temperature.

Comparing the optimum point for summer with that for winter conditions, the authors find a difference of 4.5° effective temperature.

The influence of room occupancy on the optimum temperature was accorded much study. Most of these experiments were conducted with 14 people in the test chamber, allowing a net floor area per occupant of 11.5 square feet. When the number of occupants was reduced to 8, no appreciable difference was found in the results. But when, on the other hand, the number of occupants exceeded 20, the comfort votes were noticeably affected. Under these conditions, there exists a difference of 1.4° in the probable optimum effective temperature. They conclude from these data that one might expect to find a lower optimum temperature in auditoriums and schoolrooms than in residences and offices. An effective temperature chart with superimposed comfort zones is presented.

In order to obtain further data on the subject of optimum temperature conditions, the authors conducted an inquiry into the type of underwear worn by Americans and Canadians. This information was obtained from 80 clothing stores located in 30 different cities. The conclusion is drawn that some wool and some light weight cottons are worn at all seasons of the year, no matter what the temperature may be. It is the belief of the authors that the difference in the optimum effective temperature between American and English persons is due, in some measure, to the difference in the clothing habits of the two peoples.

[This contribution is an exceedingly valuable one. For the first time, winter and summer comfort zones are plotted on the same scale and, to the best knowledge of the reviewer, air motion of from 15 to 25 feet per minute is credited with its proper place on the comfort chart.]—C. P. Yaglou and Philip Drinker, *J. Indust. Hyg.*, X, 10: 350 (Dec.), 1928. L. G.

Occupational Poisoning in the Manufacture of Luminous Watch Dials—The author in this detailed article appearing in two issues of the *Journal of the A. M. A.* expresses great surprise that a leading authority should claim radium poisoning in watch dial painters to be an obscure disease. The number of girls exposed in the New Jersey cases was about 800 between 1917 and 1924, but there were never more than 250 girls working at one time. Among these employes have occurred 15 known deaths in which the so-called radium poisoning is strongly suspected, and it was proved to be a cause of death in 5 cases. The author then discusses luminous painting; the chronological order of events in the New Jersey cases; the death from aplastic anemia of Sabin A. von Sochocky, the originator of the formula, November 14, 1928; the litigation which has occurred; the author's interpretation of the disease; special symptomatology; diagnosis during life; the methods for detection of radioactivity; the diagnosis after death which is essentially evidence of severe anemia, jaw necrosis, the radiation ostitis in other bones, secondary sepsis, the photographic findings of radioactivity, etc.; the prognosis and treatment; the future prophylaxis in the watch dial industry; and the matter of criminality in the New Jersey cases.—Harrison S. Martland, *J. A. M. A.*, 92, 6: 466–473; and 92, 7: 552–559 (Feb. 9 and 16), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Utilization of the Iron of Meats as Compared with Other Protein Foods—This paper is a progress report of an investigation of the utilization of the iron of protein foods for growth and other normal functions of albino rats, the especial purpose of which was the development of evidence as to the specific values of meats in comparison with other protein foods as a source of iron in human nutrition.

In a study of the specific effects of meats and other protein foods on the iron content of the growing albino rat, 74 rats were fed, in most cases individually, from the time of weaning, for periods usually of 5 weeks, after which iron was quantitatively determined in the entire body minus the alimentary tract.

Skimmed milk powder, whole milk powder, beef muscle, beef kidney, beef brain, beef liver, navy beans, hen's egg and peanuts were so included in diets that in each case a single protein food constituted the sole source of protein and iron. When skimmed milk or whole milk powder was used as the sole source of protein and iron, the growth was excellent, but during 5 weeks' feeding the iron content of the bodies of the rats was reduced to 50 per cent of the normal, and after 7 months' feeding on such diet, female rats were unable to rear their young. The growth from the egg diets was excellent; from the muscle, liver and kidney diets, fair; and from the brain, bean, and peanut diets, poor.

The iron content of the rats which received the meat foods was apparently normal in each case. The iron content of the rats fed on egg was much lower, and that of rats which received peanuts was lowest of all. Each of the seven protein foods studied, other than milk, was much superior to milk as a source of dietary iron for growing rats.—R. C. Miller, E. B. Forbes, and C. V. Smythe, *J. Nutrition*, 1: 217 (Jan.), 1929.

Salts in Milk and Their Importance in Dairy Work. I. The Acidity of Milk—This article emphasizes the importance of the milk salts in explaining the acidity and variations in acidity of milk. The individual salts, the amounts of which vary widely in milk, are important in explaining many phenomena in dairying and especially in dairy manufacturing. It is pointed out that the ash of milk contains the elements calcium, magnesium, sodium, potassium, iron, copper, chlorine, phosphorus, sulphur, oxygen, and carbon in various combinations, and that the salts formed should not be grouped and reported simply as "ash." Attention is directed to the fact that there is no lactic acid present in fresh cow's milk and that the acidity of such milk is due to monobasic phosphates, to dicalcium phosphate in the presence of other soluble calcium salts, to casein, carbon dioxide and citrates. The part which each one of these factors plays in producing acidity is discussed. Due to the wide variation in the salt composition of milk, there is necessarily a wide variation in the acidity. The average acidity of fresh milk is 0.14 to 0.15 per cent, the extremes found so far being 0.1 to 0.26 per cent. The composite milk from some herds has been found to have an acidity as high as 0.23 per cent. Since the acids present in such fresh

milk are much weaker than lactic acid, these high acid reactions are not objectionable.

In terms of pH such high acid fresh milk is shown to be of the same real acidity as a milk of a lower titratable acidity.

The author states that it is unjust to reject or condemn milk solely on the basis of an acid test, since some fresh milk of Grade A quality, containing less than 10,000 bacteria per c.c., may contain acid as high as 0.18 per cent. It has been found that acidity of fresh cow's milk is independent of the kind of feed given the animal, and is quite fixed and characteristic of any cow.—H. H. Sommer, *Milk Dealer*, Jan., 1929, p. 49.

Mussel Poisoning—Previously (*A. J. P. H.*, 17, 10: 1094 (Oct.), 1927) reference was made to an article reporting cases of mussel poisoning in California during July, 1927. The present article is a more extensive discussion of the cases, their symptoms, and the probable nature of the toxin. A group of 102 persons were involved in the 1927 outbreak in California. There were 6 deaths. The victims of the poisoning had eaten steamed, cooked, or raw mussels of one of the Pacific Coast varieties (*Mytilus californianus*), freshly gathered in different places which are located approximately 45 miles south and 50 miles north of the Golden Gate. The symptoms of the poisoning are primarily peripheral paralysis which may vary from a slight trembling and numbness about the lips to a complete loss of power in the muscles of the extremities and neck, and to death by respiratory failure. In a moderately severe case, the tingling, stinging sensation around the lips, gums and tongue would develop from 5 to 30 minutes after the consumption of the mussels. This was regularly followed by numbness or a prickly feeling in the finger tips and toes, and within 4 to 6 hours the same sensation would progress to the arms, legs, and neck so that voluntary movements, as for example raising of the head, were made only with great difficulty. In all cases of moderate severity this ataxic weakness and stiffness of locomotion was accompanied by a peculiar feeling of lightness. Incoherence of speech was noted in one of the fatal cases; vomiting was inconstant; diarrhea and abdominal pain were not recorded in the untreated cases.

Records of the carefully controlled cases showed the average temperature to be slightly subnormal (mean 98° F.). The pulse was firm and slightly accelerated.

The poisoned shellfish involved in the 1927 catastrophe originated from at least 14 different areas or beds on the open shore line of the Pacific Coast. Commercial mussels obtained from various places of the San Francisco Bay were not connected with any of the poisoning cases. In size, coloring, and consistency of the shells, the poisonous mussels differed in no way from those which were found to be non-toxic. No abnormal taste or odor was noted. In fact, many of the patients commented on the fact that the mussels tasted unusually good. When examined at the laboratory, every one of the staff who opened the fresh and living mussels noted a peculiar pungent, nauseating odor which was particularly marked in the highly poisonous mussels. It is justifiable to consider the irritating odors of toxic mussels resembling spoiled meat infusion as abnormal.

The digestive gland (liver) of the highly toxic mollusks was always enlarged, dark greenish, and friable. While data are incomplete on the distribution of the poison in the mussels, in two experiments the liver was considerably more toxic than the mantle tissue, but in two additional tests the [illegible] upon examination of mussels

lected along the entire Pacific Coast, it was found that in July the mussels at localities along the coast as far south as the Pacific Grove, and even along the Farallone Islands in the open Pacific, were toxic. Paralytic mussel poisoning has been observed in the months of May, June, July, August, September and October, but never during the winter months. This fact gives rise to the impression that this seasonal occurrence may in some way be associated with the spawning period of the mollusks. In studying the actual nature of the toxin present in the mussels, it was concluded that the mussel poisoning is not due to specific bacteria. Chemically, the toxin is apparently a quaternary (or possibly tertiary) amine. It is not identical with mytilotoxin described by Brieger.

It was shown that the objects on which mussels grow have no influence upon their toxicity. It was further shown that the toxin is not a decomposition product, and that decomposition of the mussels actually decreases the toxicity and finally destroys the poison entirely. No correlation was established between the toxicity of mussels taken from above or below the low water level. After considering the question of whether the toxicity of mussels is the result of an actual disease from which the mussels are suffering, it was concluded that mussel poisoning is not due to the direct action of the bacteria or to their toxins, but is the result of a promptly acting thermostable poison which has all the properties of a "sex poison." Continuous observations and more extensive chemical and physiological metabolism studies are required in order to solve the problem of mussel poisoning.—K. F. Meyer, H. Sommer, and P. Schoenholz, *J. Prev. Med.*, 2: 365 (Sept.), 1928.

The Vitamin B Content of Wheat Bread Baked with Varying Amounts of Yeast (Über den Vitamin-B-Gehalt von unter Zusatz verschieden grosser Hefemengen Gebackenen Weizenbroten) —The vitamin B content of wheat bread as usually baked is very slight. Vitamin B deficiency in pigeons which have been fed polished rice cannot be overcome by means of wheat flour, or ordinary wheat bread, nor can young growing rats be protected from vitamin B deficiency by feeding such bread. The authors state that a wheat bread weighing about 350 g. contains 280 g. of flour and 5 g. of fresh yeast, and they wished to find whether it was possible, through increasing the amount of yeast, to increase the vitamin content of the bread, especially to such a point that the bread might be designated as a source of vitamin B. Three types of bread containing, respectively, 5, 15 and 30 g. of yeast were used in feeding pigeons and young rats, which were on diets otherwise deficient in vitamin B. The pigeon experiments showed that with increasing amounts of yeast used in baking, the vitamin B content of bread can be increased so that the bread gains in protective power against vitamin B deficiency.

In young rats, bread containing 5 g. of yeast did not prevent avitaminosis. The use of 15 g. of yeast showed a somewhat better result, but with the use of bread baked with 30 g. of yeast, a growth, not at all the optimum but nevertheless satisfactory, was accomplished. It is concluded that by increasing the amount of ordinary yeast used in bread baking it is possible to increase the vitamin B content of the resulting bread, even when practically vitamin B free wheat flour is used. The amount of wheat used must be greater than ordinary, and must be at least between 15 and 30 g. Bread so made would not be wheat bread in the usual sense, but would become really a "yeast bread."—Arthur Scheunert, Martin Schieblich, *Biochem. Ztschr.*, 202, 8: 380 (Nov.), 1928.

A Poison Produced by B. Enteritidis and B. Aertrycke Which Is Active in Mice When Given by Mouth—This paper presents the results of experiments in which bacteria of the enteritidis and aertrycke types and their products were given by mouth to mice, which are susceptible to spontaneous infection by this route with these organisms. Seventeen strains of paratyphoid bacteria isolated from foods or rodents, or from persons infected during food poisoning outbreaks, produced fatal infection in 100 per cent of mice to which they were fed. These strains included 7 of *B. enteritidis*, 9 of *B. aertrycke*, and 1 of *B. Shottmülleri*. After studying the toxicity of living, boiled, autoclaved, and autolyzed washed cells, as well as whole unaltered, boiled, autoclaved, and filtered fluid cultures of 17 food-poisoning strains, it was concluded that apparently there is often something produced in broth, chopped meat, and beef heart cultures of *B. enteritidis* and *B. aertrycke* that is toxic for mice when given by mouth. When boiled broth cultures and Berkefeld *N* and *W* filtrates of broth cultures of these strains were fed similarly to mice, a mortality of approximately 40 per cent occurred.

When whole unfiltered cultures in beef heart medium are boiled or autoclaved, and then fed to mice, the mortality is often from 40 per cent to 100 per cent. Feeding autolyzed, boiled, or autoclaved suspensions of the washed bacteria had little, if any, effect. Filtrates of 24-hour cultures produced a higher mortality than those from cultures which were incubated for longer periods of time. There was no great difference in the pathological picture presented in the necropsy between mice receiving living cells and those receiving sterile materials derived from them. The greatest mortality among the mice fed living cells, and from which the organisms were recovered, was between the 4th and 9th days; whereas, among the mice fed with other materials and from which no paratyphoid bacteria could be isolated, it was between the 7th and 14th days.

The poison described in this paper is not injured by boiling, or by ordinary autoclaving. In its remarkable heat stability this poison resembles the other toxic materials which have been described in the paratyphoid group, but its surprisingly long incubation period seems to separate this toxic substance quite definitely from that responsible for the violent gastrointestinal symptoms occurring in man after eating foods containing these bacteria, and from any other toxic product of these bacteria that has yet been described. Further investigation will be necessary before it can be determined whether this toxic principle is a product of the bacterial cells or a chemical poison formed by the action of microörganisms on the constituents of the medium. The recovery of *B. aertrycke* from mice fed *B. enteritidis* and from mice fed autolysates of both *B. aertrycke* and *B. enteritidis* lends further support to the conclusion that rodents are sometimes carriers of the organisms causing food poisoning.—Sara E. Branham, Lucile Robey, and Lois A. Day, *J. Infect. Dis.*, 43, 507 (Dec.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

A Review of School Health Work—In this paper, Dr. Rogers speaks his mind frankly and fully on conditions and tendencies as he sees them. Speaking as from a tower of vantage, he tells us what he sees:

First, there is still lack of intensive training on the part of the school teacher who, after all, is really the one upon whom most reliance must be placed in promoting health habits. Also there is lack of appreciation of the need of getting the coöperation of parents. Our supply of money, too, is limited but it can be made to go further. The interdependence of mind and body is not yet realized.

It is evident that we are not yet in a position to apply adequate tests to determine the value of our health educational measures. But we should seize every opportunity to get what information we can through experiments with adequate controls. The author goes on to point out the absurdity of some of the contradictory things we teach under the guise of health education and the unjustifiable exactness with which some public health workers lay down the law. He quotes the delightful remark of Lord Kelvin to a student: "Your figures are far too exact to be accurate." School living conditions come in for a bit of criticism, and a quizzical glance is turned on open air schools and the ventilation problem.

In spite, however, of obvious defects and inconsistencies in our school health program, there is good reason, the author believes, for thinking that progress is constantly being made. He holds up to view the ideal that "Only a person possessed of high purpose begins to appreciate what health means."—James Frederick Rogers, M.D., Dr.P.H., A Review of School Health Work, *Trans., Fifth Annual Meeting, A. C. H. A.*, 1928.

Medical Service in a Continuation School—Is the medical supervision we give the school child as good as we think it is? Nobody knows, thinks Dr. Lewinski-Corwin, and he suggests that those in charge of a city's finances should have better proof of its value than "the say-so of goody-goody individuals or citizens' committees."

With such feelings in the background, the authors of this paper have taken part in a study in the continuation schools of New York City, having for its purpose "to study adolescent child life in relation to occupation and the formation of effective standards of guidance in occupational adjustments and physical fitness."

This continuation school work aims to give the pupils a thorough physical and psychological examination under the most favorable conditions. Both health and education departments are coöperating in the study. Adequate hospital contacts are made to insure prompt treatment of remediable defects.

As to the follow-up procedure, an effort is made to get both pupil and parent interested. It has been found that interest comes more readily in this class of pupil whose contacts with the world of work have given him some idea of the economic value of health. For 4 consecutive weeks the pupils are recalled for follow-up purposes. That failing, a personal letter goes to the parent. The next step, in case of fail-

ure, is a home visit by the teacher. It has been found that under this plan it has taken on an average about 3 months to get remediable defects corrected. And there is no guessing about this corrective work: a careful check-up is made.

The fact that so many children with remediable defects are to be found in the continuation schools casts serious reflection on the way health supervision is being carried on in the elementary schools.—E. H. Lewinski-Corwin, Ph.D., and Alice E. Paulsen, Ph.D., Medical Service in a Continuation School, *Trans. Fifth Annual Meeting, A. C. H. A.*

Raising Our Average of Corrections—Three-fourths of our school children have one or more physical defects needing correction. The question is, how can we raise the average of correction of these defects? The author assumes that three factors are involved: the discovery of the defect, convincing the parent of the need of its correction, and offering facilities for correction within the means of the parent.

To discover defects we must have physicians skilled in school work as well as in general medicine. It is not practicable to employ specialists. To get such school physicians, postgraduate courses should be offered to which the physician should be sent at the expense of the municipal authority responsible for school health supervision. Extra salary should be paid those who have taken such courses. The same should hold true for school nurses.

Right here Dr. Cornell offers the interesting suggestion that nine-tenths of existing defects can be discovered without removal of clothing other than coat and shoes. He further suggests two kinds of examination, one the simpler kind indicated above—required by law; and another more complete optional one.

After a word on the waste involved in having the nurse spend too much time on minor skin affections and the like; the sending home of unwarranted notices to parents; and the part that the school teacher can play in the detection of defects; the writer goes on to the persuasion of the parent and child. In his experience "it may be said that in the poor and ignorant element of the population, medical inspection without the service of a nurse is a failure." The teacher, he thinks, is an even more powerful agent, but is too busy to take the trouble. The child can be made to bring about the correction of his own defects if school competition is judiciously employed.

In speaking of the facilities ordinarily available for the correction of physical defects, the author points out present shortcomings and evidently would like to see more free service even where the social service worker might protest.

Interest is expressed in greater attention on the part of the family physician to the health of the children of his clientele.—Walter S. Cornell, M.D., How Can We Improve Our Procedure for Correction of Physical Defects, *Trans., Fifth Annual Meeting, A. C. H. A.*

Correction of Defects—Discussing the correction of physical defects in school children, Miss Chayer believes that "one of the prerequisites for a program of correction of defects is a leisurely, attitude-forming health examination," one with the child's parents present. Such an examination probably would be given only once in two or three years. Then, too, it is essential that the medical examiner be a person of conservative judgment, especially in the matter of tonsil removal. An early start on the program is important—in the kindergarten rather than in the high school. Preschool work is more important still.

Lastly, there must be a constant checking up on results, and measures

should be discarded—no matter how well established—if they do not produce results. In Miss Chayer's city they discouraged the use of milk at school except on the part of children who were failing to gain, despite the excited protests of the milk dealers as well as of certain parent-teacher association members. (One can imagine that this took courage.)

Miss Chayer believes the classroom teacher holds the key to the correction program because she "knows how to create those attitude-forming situations which make for the success of our efforts."—Mary Ella Chayer, R.N., Discussion of a paper on the Correction of Defects, *Trans., Fifth Annual Meeting, A. C. H. A.*

The Child with Potential Heart Disease—Dr. Kerley's article touches tremendously important and at present much neglected points in diagnosis and treatment of potential heart conditions in children under 12 years of age.

No progress in alleviation or cure of organic, acquired heart disease has been made in the last 40 years, in Dr. Kerley's opinion, though he does not discredit the efforts made to improve conditions for the child with heart disease.

The importance of early history is very great; "it was rare that the early history was not sufficiently suggestive to stamp the case as potentially cardiac" in the great number of cardiac patients that Dr. Kerley has handled. Warning signals are muscle pain and stiffness, sometimes joint pains, pains in extremities day or night. Restless sleep and the complaint of tired legs are also significant. Children who complain of muscle and joint pains, especially on wet or damp days, are potential heart cases. In such cases immediate removal of the tonsils regardless of appearance is demanded. The small buried diseased tonsil may be a serious focus of infection.

The question arises—does heart action show impairment? Irregular or rapid heart action disturbs parents and many physicians; also the presence of an apparently pathological murmur. A point to remember in this connection is that the pulmonic second sound in children is almost always louder than the aortic. Such conditions are often diagnosed as heart disease or potential heart disease but are not heart disease in any pathological sense.

Dr. Kerley describes a type of child especially susceptible to the infecting agencies that cause heart disease, and states that such a child "possesses what is termed a favorable soil and may be recognized and belongs to one of three groups:

Group 1. Those who have or who have had rheumatic fever.

Group 2. Those who have or who have had chorea.

Group 3. Those who complain repeatedly of pain in the extremities which may not be accounted for by trauma or disease."

A particularly susceptible child may be classified as belonging to the three groups. Heart disease in children so afflicted may be prevented in many cases by the eradication of disease foci; and by the use—at first persistent and later interrupted—of salicylic acid alone or combined with an alkali.—C. G. Kerley, M.D., *J. A. M. A.*, Feb. 16, 1929.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

National Conference of Social Work—The program for the fifty-sixth meeting of the National Conference of Social Work, June 26–July 3, and the 32 kindred groups meeting at the same time in San Francisco, will be particularly colorful this year since emphasis is to be placed on the latest developments in social work in the states where the Mexican, Chinese, Japanese and Indian groups form distinctive social problems.

The results of recent crime surveys are to be presented before the conference. Dr. George Kirchwey of New York, former warden of Sing Sing prison, is to be the chairman.—*Red Cross Courier,* 8, 5: 5 (Mar. 1), 1929.

Two Scholarships for Women in Health Education Field—Two full tuition scholarships are available for women in the field of health education at the Massachusetts Institute of Technology (Department of Biology and Public Health) for 1929–1930. These scholarships cover the full scholastic year, beginning in September and closing in June.

One, and perhaps both, will be awarded to candidates recommended by the National Tuberculosis Association. The right, however, is reserved to give one to another candidate if an application is received from one whose need and qualifications seem to be distinctly greater than that of any candidate applying through the National Tuberculosis Association.

The awards will be based upon the nature and quality of the previous academic work of the applicant, the ability which she has already shown in professional work in the field of public health or education, her need of scholarship aid and the probable value of her further contribution to health education.

Through an affiliation between the Massachusetts Institute of Technology and the undergraduate School of Education of Harvard University, those who wish to take courses in education while studying at the institute may do so without additional fee at either Boston or Harvard University.

The scholarships will be awarded June 25, 1929, and applications should be received not later than June 1. All those who are interested in these scholarships are invited to write to the Child Health Education Service of the National Tuberculosis Association, 370 Seventh Avenue, New York, N. Y., for application blanks.—*Health News,* 6, 9 (Mar. 4), 1929.

Posture, Health, and Efficiency—The complexity of civilization causes lack of adaptability between man's daily life and his physical and nervous make-up. Life has been intensified by the invention of the telephone, radio, automobile and aeroplane. These have enriched our lives, but have added strain which will bring physical and nervous disaster unless precautions are taken when the individual is very young. During childhood there should be no encroachment on the nervous and physical reserves of the individual. Great emphasis must be placed on the dangers of fatigue, and more thought given to methods of keeping fit.

Good posture and avoidance of fatigue are among the most fundamental requirements of general efficiency. The importance of this in adults and older children has been pointed out, but little

attention has been paid to posture of children between 3 and 12 years of age. The best place for research concerning the standards of posture for young children is the nursery school.

Figures obtained from adults show 3 hereditary body types: short and stocky, long and lanky, and average. Either extreme finds the establishment of good posture more difficult than those of average build. As yet it has not been determined which type in the course of growth is naturally helped properly, or in what degree apparently bad bodily mechanics are pathological, or in what degree they are merely the result of temporarily disproportionate growth of one part or another. To show this, records should be made of the posture of children at intervals of 6 to 12 months.

Records should be accurately kept which will show the following: height, weight, illness recorded to show effect on development, hours and type of play, amount of rest and sleep.

Postural records should include lateral and anteroposterior photographs of the nude body both sitting and standing in the positions assumed unconsciously, and in those which the child has been trained to take. These should be taken every few months to indicate the results of posture training. The natural trend of a young child under ideal conditions is toward good posture. Consequently, it must be determined what conditions are ideal for each stage of growth, and provide these conditions as nearly as possible.

After determining the standards, the problem of suitable posture training, if desirable, will not be simple. All elements of well-being, both mental and physical, must be constantly kept in mind. Play designed to develop a balance between the muscles will lead to natural assumption of good posture. Undue weakness of muscles in relation to the rest of the body should be studied and the cause determined. Some cure for the cause must be found.

Adaptation of a child's environment to his comfort and needs facilitates training in posture. Chairs and desks can be adjusted to the individual. Beds, pillows, and mattresses should be so arranged that it is difficult to fall into undesirable positions.

The benefit of many months of training can be lost in a brief period of convalescence. Attention to fatigue is essential in hastening recovery. While the patient is in bed, his position should be changed frequently. When he begins to move around again, activity should be resumed gradually.

Poor posture may lead to many ills. The " business man's stoop " and the " debutante slouch " cause many to become old in their youth. The mental growth of most individuals is retarded by the fatigue and strain which accompany poor posture.

On the other hand, an individual who is well set up is almost without exception radiantly healthy, unsusceptible to disease, and mentally efficient. Postural training may be therapeutic as well as prophylactic. Nothing fundamental, however, can be accomplished until fatigue, the great American ailment, is eliminated.

Success in correcting a majority of the postural faults in adults will help in teaching correct posture to children, because they learn so much by imitation. The setting of a good example will facilitate the educational problem. Better posture is one factor which will aid in obtaining success in life.—Fritz B. Talbot, M.D., Posture and Efficiency, *Pub. Health Nurse,* 21, 1: 8 (Jan.), 1929.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Something for Visitors to Do—The Germans know that exposition and museum visitors like to do more than pass along an aisle looking at displays. They have developed numerous devices by which a display is revealed through some act of the visitor. A lever is pulled, a button is pressed; the visitor puts his weight on a platform, or looks through an imitation telescope—and then lights flash, slides move, one scene gives way to another, or some other action follows.

Cafeteria Style Exhibits—Various devices could be worked out whereby some action on the part of a visitor will flash lights or move something or start some motion.

By stepping on a platform an electrical contact may be made which will flash lights—or start an automatic stereopticon—or start an electric train.

Or a push button may do something of the sort.

Or it may be done by gripping two short levers—controlled by heavy weights—and when the two levers are brought into contact the electrical connection is made.

Thus also a homemade hand grip may be made—possibly companion grips to be used by right and left hands at the same time.

Something may be made to move by the power of sand from a hopper—the hopper to be behind the scene—the sand, running down, goes into a bucket—by turning a handle at front of booth the bucket can be raised and sand dumped into the hopper to repeat the process—the bucket then to be weighted so that it will return to receive the sand again.

The same result might be secured by a series of small buckets carried around by a belt—in both cases the visitor will see only the wheel and some of the shaft or axle running back to the screen.

It may be that a small group of levers—in the fashion of a railroad switch tower—could be used to elevate in turn a group of pictures or illustrated diagrams—or the same device could be applied to the bars of an upright or horizontal diagram—each bar to be brought into sight by pulling a certain lever.

And so on.

(The basic mechanism for some of the above might be worked out even before the subject matter has been selected.)

A Contest Idea—One of your newspapers may be interested: In parallel columns, list a group of questions and the answers, but do *not* place the right answers opposite the right questions. The problem is to match the questions with the correct answers.

Questions	Answers
1—.....	A—(Answer to No. 2)
2—.....	B—(Answer to No. 4)
3—.....	C—(Answer to No. 3)
4—.....	D—(Answer to No. 1)

The questions may concern any given disease or health problem, or the work of the health agency. A newspaper might be interested in a series of such question lists, some simple awards to be given on the basis of both accuracy and

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

neatness—the second quality to extend the range of competition beyond merely getting in the first correct set of answers. You may consider the desirability of adding to every list a question like: "Where would you write, telephone or call for further information?"

The reader may be instructed to run oblique lines from the questions to the right answers, or you may tell him to list them: No. 1—D, No. 2—A, No. 3—C, No. 4—B, etc.

Exhibit Ideas from Books and Other Sources—Many ideas to adapt to exhibit or display use may be found in books on handicraft or home amusements.

Toy stores will suggest forms which may be made over and be used to express a health idea or fact.

Window displays will include devices which may be copied or adapted.

A Medical Information Bureau—The recent and phenomenal progress of modern medicine, and particularly of preventive medicine, necessitates the development of a direct and intimate channel of communication between the practitioner and the community. This is essential, not only that the public may learn to take advantage of the constant advances of modern medicine, but to the end that it may be protected against the hordes of charlatans, quacks and misguided zealots who, strange to say, thrive more than ever in this day of presumptive enlightenment. In appreciation of the needs of our day and society, the New York Academy of Medicine and the Medical Society of the County of New York have established a joint Medical Information Bureau. The aims of this bureau are to facilitate the dissemination of authentic information on medical and public health matters, to stem and curtail quackery and to promote a better understanding between the public and organized medicine.

—From a folder describing the Medical Information Bureau of the New York Academy of Medicine and the Medical Society of the County of New York. For a copy, address Iago Galdston, 2 East 103d St., New York, N. Y.

Congratulations! Now It Can Be Read!—Entering upon its eighth year the *Weekly Bulletin* (Calif. Dept. of Public Health) appears

. . . in a larger form, enabling the use of a larger size of type and permitting the use of graphic illustrations whenever an occasion may demand. The California State Department of Health began this weekly publication in February, 1922. The New York State Department of Health began publishing its weekly *Health News* two years later in January, 1924. The Ohio *Health News*, published bi-monthly, began in 1925. The Illinois *Health Messenger*, a bi-monthly, was started at the beginning of the present year. All of these publications superseded monthly journals, because the interval of thirty days between issues prevented the rapid dissemination of useful information relative to the prevalence of communicable diseases and their control. The New Mexico and Iowa state health departments now issue mimeographed weekly bulletins. Time has demonstrated the value of the weekly publication and public health workers throughout the state have emphatically stated their preference for it.

—*Weekly Bulletin.*

To New York is due credit for establishing the size and style of the printed weekly bulletins. To the list of mimeographed bulletins should be added that of Connecticut which supplements, or is supplemented by, a monthly printed bulletin.

Social Work Publicity Council—That is the new name of the Committee on Publicity Methods in Social Work, adopted by a big majority in a mail note. Nothing else is changed. The *News Bulletin* continues as the only publication devoted solely to publicity methods. The next series of meetings and exhibits will be held at San Francisco, Calif., June 26–July 3.

MOTION PICTURES

If your amateur movie friend wishes to go a step further and help you in producing a "talkie" for neighborhood production he will wish to study three methods for phonograph synchroniza-

tion described in *Movie Makers*, 105 West 40th St., New York, N. Y., Mar., 1929. *25 cents.*

The production of "Many Happy Returns" is announced by Universal Cinema Company, Indianapolis, Ind.—"a human-interest story on the importance of periodic health examinations." Did any recognized health worker supervise production of this picture?

"The Garden of Childhood"

. . . is a one-reel film which condenses into 12 minutes the important events in a well-cared-for child's day. The title suggests the analogy between the loving care a wise mother gives her child and the intelligent efforts of the successful gardener. The three children of the Rogers family eat the wholesome food that is placed before them, and are given the advantage of wise guidance in nursery school and kindergarten. They live a well ordered routine of rest, play and sleep. On the day of the story the children are taken to the physician for their health examination. One is immunized against diphtheria, another vaccinated against smallpox. Mrs. Rogers goes to a class where a nurse tells how to protect against communicable diseases, how to plan the child's diet, and how to make suitable clothes. The day ends with a bath, a quiet period, and early bedtime "to sleep the clock around." The picture has no so-called dramatic plot; the children live their story simply and naturally. The film should be a useful conclusion to any talk on various phases of preschool child hygiene. It is intended solely for that purpose.

—Free from the John Hancock Mutual Life Insurance Company, Boston, Mass.

EDUCATIONAL MATERIAL

Raymond S. Patterson may well be proud of "That Mean Cold," an 8-page booklet, his first production as director of health education for the John Hancock Mutual Life Insurance Company, Boston, Mass. *Free.* Page size, type size, double page headings, text, practical suggestions, and other detail go to make up a booklet many will actually read. Personally, I am not convinced that the tint block under the initial letters is good. Be sure to ask for samples.

A pre-view of *Three Portraits*, a John Hancock booklet for the early Diagnosis Campaign in April, shows promise of an equally readable publication. Get on the mailing list for copies when it comes out.

"Ten Commandments for Keeping Baby Well," Department of Health, New York, N. Y. Effective use of bold face type for the "commandments," with explanatory comment simply written. *Free.* On the cover page: "If the baby is sick and you cannot afford to pay a physician, *notify* Department of Health" (followed by list of various borough offices). The italicized word marks the one doubtful point in the booklet. Will the mother who "cannot afford" a physician readily know *how* to "notify" the department?

"Cheese in the home," "Peas in the diet," and "Cranberries in the diet," issued by College of Agriculture, Madison, Wis., are noteworthy for the excellent statements of "Why use . . ." appearing on the several inside cover pages. "Milk—the Best Food" carries a "Digest" (which should have a livelier title) which combines an outline of the subject matter with a table of contents—an idea some may care to adopt. *5 cents* each.

"The Baby and You," a 40-page pamphlet, Massachusetts Department of Public Health, is one of the best of the kind—in text, illustrations, and paper. Good introductory statement following the cover page. *It has a table of contents.*

The Tennessee Tuberculosis Association, Chamber of Commerce, Nashville, has reprinted in leaflet form the *Saturday Evening Post* editorial on "Buying Health." Striking title page—but the shiny paper seems unnecessary. *2 cents.*

A 4-page folder on "How to Conduct an Isolation Period in the Home" is being used by Newark, N. J., Winston-Salem, N. C., and Hamilton, Ont.,

Health Departments. *Free,* of City Health Department, Baltimore, Md. A more interesting paper might be used for this folder—an antique or a slightly rough surfaced paper, for example.

"Safeguarding Your Health from Tuberculosis," a 28-page booklet by Department of Health, Winston-Salem, N. C., with credit to New Haven, Conn., Department of Health for "much of the material." An effective, popular description, with a page to each of the following and other topics: "The Roll of the Private Practitioner," "Importance of Sputum Examination," etc. Includes diagram showing coöperation of public and private agencies. *Free.*

A 4-page folder on vitamins is being prepared by Bureau of Chemistry and Food, City Health Department, Baltimore, Md.

"Headaches: Do You Have Them?"—11 by 16 inch poster, mostly words. Good text. Employers' Mutual Liability Insurance Company, Wausau, Wis. *Free.*

These three booklets of the Metropolitan Life Insurance Company are diverse examples of well printed health education material:

"Just a Cold? Or—" 8 pages. *Free.*

"Sunlight the Health Giver," 10 pages. *Free.*

"Headaches," 8 pages. *Free.*

DATES AHEAD

April 21–27—Better Homes Week. "Guidebook for Better Homes Campaigns," Better Homes in America, 1653 Pennsylvania Ave., Washington, D. C. *10 cents.* Includes campaign ideas available for other uses.

May Day—Child Health Day. Address American Child Health Assn., 370 Seventh Ave., New York, N. Y., for organizer in your state, and publications.

For May Day and other days—summer or winter: "*Play Day*—The Spirit of Sport," by Ethel Perrin and Grace Turner. American Child Health Assn., 370 Seventh Ave., New York, N. Y. 77 pages. *Many illustrations.* "A team for everyone and everyone on a team." *35 cents.*

TITLES AND PHRASES

"Every child well bred, well fed, wisely led"—Indiana State Board of Health.

"A goggle that is hanging on a nail is no better than a glass eye"—Employers' Mutual Insurance Liability Company.

"Grappling Versus Nibbling"—*Mental Hyg. Bull.,* 370 Seventh Ave., New York, N. Y.

"If your child contracts diphtheria, what excuse can you give?"—Detroit Dept. of Health.

"Make the common cold uncommon"—Indiana State Board of Health.

"Why die so Young?"—A Red Cross Nutrition Service talk.

DIPHTHERIA

How immunization of practically 100 per cent of the children in two towns of 6,000 combined population was made possible is told in *Prevention,* New Brunswick Dept. of Health, Fredericton. Jan.–Feb., 1929.

Immunization success by means of a motion picture and a lecture, with Parent-Teacher Assn. coöperation, in a community of 1,500 is described in *Ill. Health Messenger,* State Dept. of Health. Feb. 15, 1929.

"What Is Being Done about Diphtheria?" a WEAF radio talk, by D. B. Armstrong, M.D. State Charities Aid Assn., 105 East 22d St., New York, N. Y. *2 cents.*

"Your Child Looks to You for Protection," a 4-page folder, is one to secure when planning diphtheria printed matter. A little too much red ink, the editor believes. City Health Dept., Baltimore, Md. *Free.*

REPORTING

Annual reports can be roughly classified as surveys or obituaries. The first kind not only tells what has been accomplished and how, but compares results so that those things which are lacking or poorly done are emphasized sharply by contrast. Such a report stimulates to greater and better work in the future. The second kind recites in a eulogistic but monotonous way the deeds of the past, and serves merely as a record, which is consulted only if the occasion demands. In one sense an annual report should be like the record of a periodic health examination—designed to show up defects and to point out methods of prevention and cure.

The editor then shows that the current report of the Board of Health, White Plains, N. Y., belongs in the first class. —*Health News*, New York State Dept. of Health, Nov. 19, 1928.

"Vital Statistics of the Bellevue-Yorkville District" is significant as an illustration of possibilities in the assembly of statistical data as a basis for building a health program. The publication method illustrates the comparatively inexpensive reproduction of numerous detailed tables, together with maps and diagrams. The material was first typewritten (charts and maps drafted) and the whole reproduced by zincograph process on 49 pages, reduced to 10¾ by 8¼ inches, with a printed stiff board cover. First edition of 260 copies cost $187.50; 250 reprints costing $119.50. Copies were sent to the Bellevue-Yorkville Community Health Council, principals of public and parochial schools, state health officers, health officers of 30 largest cities, and health officials in several other countries. Copies will be supplied to JOURNAL readers upon request to Bellevue-Yorkville Health Demonstration, 325 East 38th St., New York, N. Y. G. J. Drolet, New York Tuberculosis and Health Association, supervised the report.

"Broadcast from Station 'Girl Scout' with Television Pictures," is the 1928 annual report of the National Girl Scouts, 670 Lexington Ave., New York, N. Y. *Copy free.* Of much interest to those who need not present a mass of detailed statistics in a report.

"The Hospital without Walls," a miniature report of Community Health Association, 502 Park Sq. Bldg., Boston, Mass. Beautifully done. Note use of two kinds of paper. *Copy free.*

"The Service of Print to May Day, 1928" is a 30-page pamphlet reporting the coöperation of periodicals, with classified lists showing what was done by the individual editors.

"Twenty-Five Years of Fighting Tuberculosis in Minneapolis and Hennepin County" is notable for its good cover page, including effective use of an outline map of the county and a border in silver on grey paper. There is a chronological record and also treatment by topics, with an abundance of pictures to toll the reader through the pages There is a table of contents, but it is called an index and is placed at the back—better to have been right after the title page. *50 cents.*

Unfortunately the 1927 report of New York Nursery and Child's Hospital, New York, N. Y., is out of print (copy will be *loaned* by the editor for 5 cents postage). Exceptionally pleasing example of a report covering considerable detail. Here are the specifications: 70 lb. India laid Utopian paper; cover of 65 lb. green Neapolitan; cover, title page and chapter headings in Narciss; the text in Caslon 8, 10 and 11 point. Photographs with one exception were taken by Paul Parker. Tipping in the photographs was fairly expensive, but is effective and necessary because of the interesting rough finish paper.

REQUESTS

"Can you refer me to any organization from which I might obtain height and weight charts, posture and health posters?" (For use in a large city public school.) What do you suggest?

BOOKS AND REPORTS

USEFUL BOOKS OF THE PAST YEAR

M. P. RAVENEL, M. D.

DURING the year which has passed since our last annual review, many books on hygiene and public health have been published. In fact, there appears to have been a veritable *cacoëthes scribendi.* Very few of those which directly concern health are outstanding. Many of them are along the old cut and dried lines, with nothing original in either fact or presentation, and many more are distinctly poor. We cannot but believe that the publishers are largely responsible for this deluge of poor books, some of which contain the most evident inaccuracies as to facts. Apparently any man who has large classes can have a book accepted since he can influence sales. We believe that it is time for the publishers to clean house, as it were, by exercising more care in the selection of manuscripts. As Elliot Holt has recently said in speaking of non-professional books: "Wouldn't it be more logical if publishers confined their efforts to fewer titles, each one commanding their most loyal backing and honest respect? Might not this method be better for the chosen authors themselves than being included in the deluge of publications from most firms that bewilders the public? "

In contrast to the mediocre quality of books written directly on the subject of health, we see a comparatively large number of unusually good ones on allied subjects. The growth of books on sociological subjects and mental hygiene is notable.

In the preparation of this review, the advice of others engaged in several fields of public health work has been obtained. While most of the books selected have been reviewed in our own JOURNAL, other publications, mostly American, have been examined, though British journals have also been used. In only one or two instances have new editions been mentioned, exceptions having been made in cases where the revision resulted in practically a new book, particularly outstanding in its class.

As before, we have attempted to classify the books recommended. In many instances, this has been extremely difficult, and such books have been placed in a general group. The classification given is not exact, and some will doubtless disagree with the grouping.

Technical bacteriology is represented by the following: *Newer Knowledge of Bacteriology and Immunology,* by Jordan and Falk, University of Chicago Press; *Bacterial Vaccines and their Position in Therapeutics,* by Leonard S. Dudgeon, Hoeber; *Filterable Viruses,* edited by Rivers; *Annals of the Pickett-Thompson Research Laboratory,* Volumes III and IV, Part I; and *Physiology and Biochemistry of Bacteria,* Volume I, by Buchanan and Fulmer; the three last published by Williams and Wilkins.

Since bacteriology has come to be required as a subject for general education, and is widely concerned in various manufactures and in household affairs, a general course is being given in many colleges and schools. Two excellent books designed for this purpose are: *A*

Text-Book of Bacteriology and Its Applications, by C. M. Hilliard, Ginn; and *An Elementary Text Book of General Microbology*, by Ward Giltner, Blakiston.

Closely allied with bacteriology are the courses in hygiene widely given under various names. In this class two especially good books have appeared: *A College Textbook of Hygiene*, by Smiley and Gould, Macmillan; and *Health Essentials*, by Andress, Aldinger and Goldberger, Ginn. The latter is based on the idea that many pupils do not go to college, and must receive their training in the more elementary schools.

The study of nutrition and of foodstuffs continues to occupy the attention of specialists, and their results are eagerly looked for by all interested in public health. For general reading, we can recommend: *Nutrition*, by W. H. Eddy, Williams and Wilkins; and *Food, Health and Vitamins*, by Plimmer and Plimmer, Longmans, Green. Somewhat more technical, but also adapted to non-professional readers, is *Food Infections and Food Intoxications*, by Samuel R. Damon, Williams and Wilkins. Since no single food is of more importance than milk, and so much depends upon its proper production and handling, good books on dairy science are always welcome. Among these: *Fundamentals of Dairy Science*, by Associates of Lore A. Rogers, Chemical Catalog Company; and *Dairy Bacteriology*, by B. W. Hammer, Wiley, are to be especially recommended.

The year has brought few new books on water and sewage disposal, but those which have appeared are well above the average. We can recommend: *Water Purification* (2d ed.), by Joseph W. Ellms, McGraw-Hill; *Chemistry of Water and Sewage Treatment*, by Arthur M. Buswell, Chemical Catalog Company; and *Principles and Practice of the Dilution Method of Sewage Disposal*, by W. E. Adeney, Macmillan.

The health officer is very directly concerned in administrative problems which often involve legal questions. These are well considered in *Dunn's Food and Drug Laws, Federal and State (Annotated)*, by Charles Wesley Dunn (3 vols.), U. S. Corporation; and *The Validity of the Appraisal Form as a Measure of Administrative Health Practice*, by Philip S. Platt, American Public Health Association.

In view of the great importance of health to the vast number of those gainfully employed, as well as to their employers, the lack of books on industrial disease is striking. *Prescribing Occupational Therapy*, by William Rush Dunton, Jr., Charles C. Thomas, though small, is an excellent guide. From the house of Harper come two good books: *Psychology for Executives. A Study of Human Nature in Industry*, by Elliott Dunlap Smith; and *Safety and Production*, a report by the American Engineering Council. The first is unusual, not only in its point of view, but in the admirable way in which the subject is handled. The second is devoted entirely to the prevention of accidents and does not consider health as a factor in safety.

History and biography are well represented by: *A Short History of Medicine*, by Charles Singer, Oxford University Press; *Folk Lore of the Teeth*, by Leo Kanner, Macmillan; *Max von Pettenkofer, His Theory of the Etiology of Cholera, Typhoid Fever and Other Intestinal Diseases*, by Edgar Erskine Hume, Hoeber; *Percival's Medical Ethics*, edited by Chauncey D. Leake, Williams and Wilkins; and *Fighters of Fate*, by J. Arthur Myers, Williams and Wilkins.

Mental Hygiene is too little considered and too little understood by the average practitioner and health officer. It is a specialty requiring particular training. In the past we believe that the specialists in this line have been too

aloof, but there are now books on the subject written in a style and on a level which the average man can understand and appreciate. Among these the following are recommended: *Why Men Fail,* edited by Fishbein and White, Century; *The Mental Health of the Child,* by Douglas A. Thom, Harvard University Press; *The Child in America, Behavior Problems and Programs,* by Thomas and Thomas, Knopf; *Psychology of Abnormal People,* by John J. B. Morgan, Longmans, Green; *The Problem Child at Home,* by Mary B. Sayles, Commonwealth Fund; *The Unconscious* —a symposium with introduction, by E. S. Dummer, Knopf; and *Understanding Human Nature,* by Alfred Adler, George Allen and Unwin, London.

Some unusually good books have appeared on special problems, all of which, however, touch preventive medicine and public health closely. Among these we can recommend: *The Opium Problem,* by Terry and Pellens, Committee on Drug Addictions, New York; *Cancer: A Professional Responsibility and a Public Liability,* by Albert Soiland, Appleton; *Principles of Ante-Natal and Post-Natal Child Hygiene,* by W. M. Feldman, John Bale, Sons and Danielsson; *Negro Problems in Cities,* by T. J. Woofter, Jr., Doubleday, Doran; *Chemistry in Medicine,* edited by J. O. Stieglitz, The Chemical Foundation; and *Nurses, Patients and Pocketbooks,* by May Ayres Burgess, Committee on the Grading of Nursing Schools, New York. The last mentioned of these books is a study of the nursing problem made in a conscientious and thoroughgoing style. It is of interest, not only to nurses themselves as a professional body, but to hospitals, practitioners and those who employ nurses. The book on the opium problem is the result of many years of study which embraced practically the entire world, and gives the most complete information available on the subject of narcotics, especially opium. Its value will be evident when we remember the International Congresses held to consider the question, and the vast amount of legislation passed without expert knowledge of the subject.

Our last group is those books which touch public health from several angles, some of which might have been included under previous heads or special heads: *Publicity for Social Work,* by Routzahn and Routzahn, Russell Sage Foundation; *Social Work and the Training of Social Workers,* by Sydnor H. Walker, University of North Carolina Press; *Growing Up. The Story of How We Become Alive, Are Born and Grow Up,* by Karl de Schweinitz, Macmillan; *Infancy and Human Growth,* by A. L. Gesell, Macmillan; *A Text-Book of Infectious Diseases* (3d ed. of *Goodall and Washbourn's Manual of Infectious Diseases*), by E. W. Goodall, Wood; and *The Genesis of Epidemics and the Natural History of Disease,* by Clifford A. Gill, Wood. The book on infectious diseases has been included because of its unusual character which makes it of especial value to health officers.

(*See p. XXXIII for announcement of new books*)

Epidemiology Old and New—*By Sir William Hamer, M.A., M.D., F.R.C.P. New York: Macmillan,* 1929. 180 pp. Price, $3.50.

One seldom comes across a book more provocative of thought. Anything written by the distinguished author is worthy of attention.

We are carried back to Sydenham and his "epidemic constitutions," which are considered and explained at some length. Influenza is taken as the great example of his thesis. Descriptions of the epidemics in the time of Sydenham as well as those of later years are given and compared. We are urged to break

away from the domination of bacteriological methods and to consider epidemic diseases as epiphenomena, as the outcome of the interaction between a virus and the humors of the body.

The author does not belittle the tremendous increase in knowledge due to the opening up of the new world of microscopic and even ultra-microscopic life, but holds that the macroscopic must not be lost sight of.

The book does not lend itself readily to review, containing, as it does, numerous quotations of, and references to, English writers and scientists chiefly, and many figures. While Sydenham has always been before us as one of the geniuses of medicine, the presentation and discussion of his ideas given by the author will create in the reader a still greater respect for him—in spite of some of his more or less metaphysical ideas —especially in this day when we have gone so far toward materialism in medicine. While Sydenham had ideas which modern knowledge prevents us from accepting, he was, as far as the practice of medicine went, an exponent of " that solid experience which rests upon the basis of the senses."

The book is well printed on light paper, and can be commended to all who seriously study epidemiology and the science of medicine. M. P. RAVENEL

The Health of Youth—*By Florence Meredith, M.D. Philadelphia: Blakiston,* 1928. 535 pp. Price, $1.60.

This is a work designed for use as a textbook on hygiene during the adolescent period. It seems more suitable for senior high school grades.

It is in attractive, readable form and places emphasis on health and right living, rather than on anatomy or disease. It has at the end of each chapter a summary stated as separate facts, each of which might well be used as a topic for discussion. The chapters, 22 in number, cover such health topics as: Food and Diet, the Hygiene of Eating, Fresh Air and Ventilation, Exercise, Fatigue, Bathing and Cleanliness, and Mental Hygiene.

This is a particularly good text and should well serve the purpose of a basic text for use by high school pupils, especially if it has been preceded by an adequate discussion of fundamentals during the junior high school years.

CHARLES H. KEENE

The Story of Modern Preventive Medicine—*By Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P. Baltimore: Williams & Wilkins,* 1929. 295 pp. Price, $4.00.

This " sketch," as the author calls it, is not written in the usual historical style. The book is divided into three parts. The first part, after some introductory considerations, takes up the various communicable diseases one by one. Part second is devoted to some of the physical and social conditions of health, such as ventilation, fog, smoke, housing and occupation. Part three considers physiological conditions, taking up the hormones, some deficiency diseases, foods, vitamins, and ends with a chapter on alcohol.

Some of the subjects are well considered, while others are deficient. It would seem that an important matter involving such a great controversy as was waged over the transmissibility of bovine tuberculosis to human beings would require fuller treatment, and a more correct statement of facts.

The book is marred by misspellings of proper names as well as by incorrect designations, such as the Bureau of " National " Industry where " Animal " Industry is meant. Walter Reed is said to have been on the staff of the American Public Health Service, when he was an officer in the Army. Noguchi (page 159) is credited with the discovery of the spirochete supposed to be the cause of yellow fever, and 4 pages after, a

postscript is added giving an outline of the work of Stokes in West Africa, which credits Stokes and his coworkers with having shown that the disease is due to a filter-passing virus, no mention being made of the fact that the Commission headed by Reed proved this some 26 years before. The misstatement that Lazear died from an experimental bite is again repeated, the fact being that Lazear allowed himself to be bitten by a stray mosquito which was not known to have fed on a yellow fever patient.

The book is written in the pleasant style for which its distinguished author is noted, and while it is in the main correct, it is too sketchy and contains too many inaccuracies. Apart from the poor proof reading which is evident, the book is well printed and made up, but one has learned to expect better of the publishers. M. P. RAVENEL

Hows and Whys of Human Behavior—*By George A. Dorsey, Ph.D. New York: Harpers,* 1929. 298 pp. Price, $3.50.

Deluged by letters from individuals who have become curious about human behavior since the recent popularization of the subject, and by requests from parent clubs, professional groups and business organizations, to tell them more about the whys and wherefores of our daily actions, Dr. Dorsey has written this book. It follows closely after *Why We Behave Like Human Beings,* which was one of the non-fiction best sellers of 1925, with increased demand the following year.

The *Hows and Whys of Human Behavior* is written in a much freer, more popular style than Dr. Dorsey's first book. In fact it might be accepted as a chatty discourse on the fundamentals and scientific basic facts of the complexes of human nature, the physiologic and biologic causes and results of man's daily acts. Although the author has purposely camouflaged his science by a popular coat, the reader discovers that he is presenting his subject of behavior psychology with a continuity and logic that immediately dispel any suspicion of his intent to market another best seller crammed with " slap-jack " advice for revamping ourselves so as to become immediate successes on the stock-market, in the political ring or in the social whirl. Instead, he brings out by example and scientific analysis how our behavior in adult life may be conditioned by a single incident in childhood. A man's successes or failures may be conditioned by his early environment.

Running over the chapter headings—How Much of Your Brain Do You Use? Why Do We Fall for Each Other? How Does Your Job Fit You? Why Do You Sleep So Much? Why Do Words Boss You? Why Aren't We the Happiest People in the World?—the reader finds everyday queries answered.

We were all born with a " mechanism engine " ready to go, but where and how it has gone since we were born has been determined by those under whose influence we have lived and also by our own efforts.

> You are what you are today because you were what you were yesterday. . . . You can become something different tomorrow by forcing yourself to be something different today. Your brain is limitless. . . . Load it with new sights, new sounds, new tastes, new vocabularies, new experiences. The more you use your brain, the more brain you will have to use.

The author explains " personality," that over-rated, intangible something that the business world has capitalized upon. He explains, in a manner that laymen can understand and the intelligentsia accept, the glandular mechanism which is responsible in part for our behavior. He does not talk down to his lay reader. He tells him about " impulse," " reflex," " instincts," " mechanisms " and " neurons."

This volume is as fascinating as any detective story. You are carried on from chapter to chapter, because from the outset your curiosity about yourself as an ordinary human has been aroused. Through the pages stalk everyday intimates, colleagues, who you know are the result of the so-called "early conditioning" or of not having subjected themselves to a critical self analysis. If you are in a rut, the book is an antidote. It is recommended not for one reading, but as an addition to your library to which you can turn for frequent mental stimulation and enjoyment.

A. B. TOWSE

Corrective Physical Education for Groups—*By Charles LeRoy Lowman, M.D., Claire Colestock, and Hazel Cooper. New York: A. S. Barnes & Company*, 1928. 521 pp. Price, $4.50.

"This book is presented as a theoretical and practical guide for teachers in the field, and students in training for physical education."

Written by a specialist in orthopedics and two specialists in physical education, it presents a composite view. It tries to emphasize: first, those exercises corrective in type, which may be used by the whole class or group; second, those designed to correct specific weaknesses, or deformities in definite individuals.

The early chapters are devoted to the corrective problem, the influence of posture on growth and development, body statics and types, and the technic of examination.

Several chapters are devoted to the organization of the effort in elementary, junior, and senior high schools, equipment needed, and the type of activity recommended.

A section is set aside for discussion of methods. There are also chapters on corrective games and dances.

This book contains a wealth of material on equipment and methods, and also has a large number of carefully described exercises for various types of defects. It also has an extended bibliography on corrective gymnastics, organization, methods, athletics, play, and posture. There are a considerable number of illustrations of defects and of specific exercises.

CHARLES H. KEENE

Malaria, its Investigation and Control with Special Reference to Indian Conditions—*By Robert Knowles and Ronald Senior-White. Calcutta: Thacker, Spink & Co.*, 1927. viii + 208 pp.

This is a field-worker's manual written by the professor of protozoölogy in the Calcutta School of Tropical Medicine and the Malaria Research Officer of the Central Malaria Bureau of the Government of India. It contains instructions for the diagnosis of malaria in the laboratory, the treatment to be given patients, and practical directions and the theoretical principles useful for the guidance of the malariologist seeking to find mosquitoes, to conduct a malarial survey, and to design, construct and maintain anti-mosquito measures and structures.

The breeding places and distribution of Indian anopheline mosquitoes are described and keys to their adults and larvae are given. Specifications for underdrainage of estates and plantations with a view to the reduction of breeding places of anophelines are supplied as recommended by the Public Works Department of the Malay States. There are 12 pages of bibliography.

The extent to which public health and preventive medicine have developed in India by the Indian Medical Service and by industrial and agricultural enterprises, together with the magnitude of the malarial problem in India and Malaya, have provided a wealth of practical experience of great value.

This book embodies the results of this work and should be of wide use in the tropics and elsewhere, wherever malaria occurs. CHARLES A. KOFOID

Learning Exercises in Food and Nutrition—*By Anna Belle Robinson, A.M., and Florence M. King, M.S. New York: Heath,* 1928. 164 pp. Price, $1.20.

The authors, members of the faculty of home economics education in the University of Illinois, have given in this small volume lessons in food values, meal planning, and cooking, based on actual experiments in their own classrooms. The book has been prepared with the student in mind. However, it will serve the teacher of home economics who is looking for new ways of coördinating and presenting her material and furnish an outline of definite objectives in her work. Menus for the baby, the adult, the family, the invalid, and the convalescent are suggested. The economic side of meal planning is considered. A meal score card has been worked out, but the unique feature is the grocery store score card. The appendix includes simple and varied recipes adapted to the average American family budget. A. B. TOWSE

Dairy Bacteriology—*By Bernard W. Hammer, Ph.D. New York: Wiley,* 1928. 473 pp. Price, $5.00.

As stated in the preface, this book contains the material offered in the beginning course in dairy bacteriology at Iowa State College, to be preceded by general bacteriology, which is necessary to a clear understanding of the subject. The student is also expected to have some knowledge of the standard methods of bacteriological examination of milk. Especial attention is given to the fermentation of milk which is so essential to successful dairy practice.

The table of contents, and the number of pages devoted to each subject, show that all the essentials are fairly considered. The bacteriology of milk products, including evaporated, condensed and powdered milks, is adequately treated. The last chapter is devoted to various tests which are essential in dairy practice.

We would suggest that the tendency to limit the term Malta fever to the disease carried by goats and produced by the *Br. melitensis* be recognized, that undulant fever be more fully recognized, and the term included in the index.

The book is written in clear language, is admirably adapted to the purpose for which it is designed, and can be recommended without hesitation. The printing, make-up and illustrations are excellent. M. P. RAVENEL

Nutrition in Health and Disease for Nurses—*By Lenna F. Cooper, B.S., M.H.E.; Edith M. Barber, M.S.; and Helen S. Mitchell, Ph.D. Philadelphia: Lippincott,* 1928. 574 pp. Price, $3.00.

The comprehensive nature of nutrition in health and sickness is simply and adequately presented in this volume. The facts are correctly given, and the presentation of the material is clear, understandable and substantiated by authoritative references, illustrations, tables and charts.

Although the work is intended as a manual for the student nurse, its value as an authentic reference for the various types of professional workers who need such information and yet are not nutrition specialists cannot be over-emphasized.

That the authors had clearly in mind the purpose for which the text is intended is indicated by the arrangement as well as content of the book. The individual chapters are complete in themselves and of high quality.

Part I deals with the principles of nutrition and presents the newer ideas based upon recent experimentation and

study, as well as upon the established knowledge of earlier research.

Part II has to do with food selection and the practice of dietetics, beginning with the development of cookery and the service of food, and passing on into menu planning and hospital dietaries.

Part III is confined to diet in disease. It includes the prevailing practices of leading physicians in nutrition as applied to disease.

Part IV includes the principles of cookery for the sick and convalescent, providing recipes for small quantities, since the nurse usually prepares food for only one person.

The Appendix contains tables of food values, and of 100-calorie portions, as well as practical suggestions for instructors of nutrition in schools of nursing.

There is a good Index. The printing and make up of the book are good. It should be of interest to a great variety of readers, including the thoughtful housewife, whose responsibilities to her family should stimulate her to understand more concerning the principles of nutrition and how to apply them to her needs. EMILIE G. ROBSON

Chemistry in Medicine—*Edited by Julius Stieglitz. New York: The Chemical Foundation Inc.* 757 pp. Price, $2.00.

The book is aptly described by its subtitle, "A Coöperative Treatise Intended to Give Examples of Progress Made in Medicine with the Aid of Chemistry." The point of view is thus medical rather than chemical, and the book can be read with understanding by those who have no chemical training beyond an introduction to the subject.

While the book is avowedly propaganda, the unfolding of the many examples of "progress in medicine with the aid of chemistry" is done in such a manner as to include much general information. It is not, nor does it claim to be, of a nature to stimulate the reader toward contributing to this medical progress in any specific technical way, though problems often suggest themselves during perusal. Certainly the magnitude and the extent of the contributions of chemistry to medical progress will be deeply impressed upon even the most casual reader.

There are 10 chapters, a number of which include several "articles." The first 3 chapters are general, treating respectively the significance of chemistry and its methods of attack, heredity and development, and the human body as a machine. Chapter IV might well have been included as one of the articles in chapter V, which in 4 articles treats of the conquest of rickets, scurvy, pellagra and beriberi.

Chapter VI includes a series of 8 articles on the various hormones, the chemical regulators of the body. Chapter VII, on the policing of civic life in the laboratory, has 5 articles on the laboratory control of water supply, foods, drugs, industrial poisoning, and sewage disposal. Chapter VIII, with 7 articles, treats of the alleviation of suffering. Subjects dealt with include anesthetics, soporifics and chemical aids for certain organic functional troubles.

Finally, chapters IX and X deal with the field of the war on invading germs. A series of 10 articles is given to the discussion of immunological and chemotherapeutic studies.

Although a number of authors have contributed, unity of plan is apparent in the assembling, the unevenness so often seen in such works having been reduced to a minimum. We have the benefits of diversified authority coupled with uniformity.

The one glaring example of editorial failure is in chapter IV, written by McCollum and Simmonds, on the history of the discovery of the vitamins. The names of Hopkins, Steenbock and Hess are not even mentioned, and Funk gets only a somewhat casual reference, which is derogatory.

ALLEN E. STEARN

The Daily Health Builder—*By C. Ward Crampton. New York: Putnam,* 1928. 161 pp. Price, $1.50.

This book is a handy, safe guide for the adult who is wise enough to go to his own physician for a health examination, and fortunate enough to have a physician who distinguishes between such an examination and the one devoted entirely to discovering disease—he is still more fortunate if that physician can and will prescribe the particular follow-up indicated by the findings of that examination.

All of these are premises set forth by Dr. Crampton and which the lay individual is supposed to accept before using the book. In short, while the book, entertainingly written, fully illustrated, may be easily followed by any individual, that individual should look upon any exercise askance which is not prescribed by his physician to meet his needs. Providing the ones set forth by Dr. Crampton do meet these needs he will find the reasons *why* clearly and simply stated. The fact that Dr. Crampton has discerned a need for such a text is a wholesome sign of intelligent thinking on health by the lay public.

LENNA L. MEANES

The Facts against Compulsory Vaccination—*By H. B. Anderson. New York: Citizens Medical Reference Bureau,* 1929. 127 pp. Price, $1.00.

Most of the sentences and paragraphs in this book are "quotations" or extracts from a great variety of sources, including public health officers, reputable physicians and scientists, the Constitution of the United States of America, the Declaration of Independence and other more or less official documents. In a few cases the documentation is by means of photographic copies of *marked* originals, although there is no reason to question the accuracy of the citations. The author's work was largely that of compiling and editing. In terms of his purpose, which is ostensibly to place the practice of vaccination upon a voluntary rather than a compulsory basis, but in reality to discredit the practice of vaccination in general and medical science by indirection, he has done what might be called devilishly well. That is to say, he has applied cunning and a certain sophisticated naiveté, which is irresistibly convincing to the uncritical, and which leaves the impression of a well-knit case with no room for argument. He seems indeed to have rested his case for the most part on the statements of the "doctors" themselves.

The book presents two serious defects of structure. The author offers a series of major propositions or theorems, in bold face type and boxed headings, to his main divisions and subdivisions. These theses are immediately followed, without any argument or exposition, by supporting documents or extracts from the more or less reliable and relevant authorities; and in these extracts certain passages are again placed in bold face type. The reader is instructed at the start that the main argument is to be found in the bold type, and that one can follow the essential story by judiciously skipping with the aid of this simple device—"It is not necessary, therefore, to read the light face type except where questions arise regarding the accuracy of any assertion contained in the headlines, in which case the facts are readily available." Inasmuch as the "assertions" are in the nature of conclusions or inferences, while the "facts" are presented as citations from authorities—authentic enough for the most part—the trap ought to click nine times out of ten or thereabout. The structural defects are that the documents do not always warrant the conclusions presented, and the bold face type repeatedly indicates ulterior motives. A different distribution of typographical emphases in precisely the

same material would give the unprejudiced reader a totally different set of conclusions. In a few cases one may question the selection and arrangement of statistical data (as Mr. Anderson himself invites us to question *official* statistics), but the fatal defect is present even where the documents are unimpeachable.

From the point of view of the public's basic concern in the question, this book illustrates one of democracy's major difficulties. Attacking compulsory vaccination primarily in terms of the rights of individuals to choose their own opinions on medical matters, the author might consistently build up a case for the doctrine that each one of them has a right to go to the devil or to his grave in his own way—many eminent leaders of thought would then agree with him. When he starts, however, to stress the uncertainties and ambiguities and risks that surround the history of vaccination, he shifts his position from one of civil liberty to one of technical reliability on the part of the medical profession. He is, after all, not so much concerned with the abstract principle of liberty as he is with combating the biological sciences as religious systems; and here, as everybody knows, one "opinion" is as good as another—in a democracy.

We should have more regard for the writer's intellectual integrity if we did not happen to know that he is a confirmed prohibitionist; that is to say, he is willing to agree with you and me that the machinery of government may be properly used to enforce or constrain in regard to details that we accept; but he will insist with us that it is very, very wicked for the government to use its power to enforce upon us something you and I—and Mr. Anderson—do not like. The issue eventually comes down not to an abstract principle of civil or political *right,* but to the practical question of the relative efficacy and harmlessness of a technical procedure—in this case vaccination. Mr. Anderson gives the unsuspecting reader not only serious doubt as to whether vaccination ever did or could prevent smallpox, but an uncomfortable feeling that vaccination actually kills more people than would die of smallpox—*if there were no vaccination.* Any person who (1) knows the facts, (2) feels responsible for the health and welfare of others, and (3) reads this book, will there and then either (a) feel that an outrage has been committed, or (b) withdraw to his solitude to inquire whether after all people do not get about what they deserve.

B. C. GRUENBERG

The Human Machine in Industry—*By Richard T. Dana, assisted by Arthur P. Ackerman. New York: Codex Book Company, Inc.,* 1927. 312 pp. Price, $4.00.

The authors state that the purpose of this book is to make more readily available those facts which bear upon the capabilities and limitations of mankind for work, to the end of promoting the efficiency of management and the welfare of labor. The general propositions are—first, if the man is more comfortable he will be happier and live longer; second, if we properly control the conditions of his comfort, fatigue, and health, he will turn out more work at less cost.

The subject is divided into Chapters as follows: I. *General principles* concerning the dimensions in capacity of the human machine and its monetary value; II. *Fuel requirements,* with a discussion of the question of food under different conditions of work; III. *Cooling requirements,* with a discussion of climate, a very complete statement of healthful atmospheric conditions and the methods of controlling them according to our latest theories; IV. *Fatigue,* with a competent discussion under numerous headings and relations, showing close familiarity with physiology; V.

Rest periods, to which a discussion of 20 pages is devoted; VI. *Economic hours of work,* in which numerous British and other results are recited; VII. *The relative efficiency of men and women* (18 pages); VIII. *Occupational age limits,* for both sexes, and the various relations of age to work; IX. *Industrial diseases,* in a wholesome discussion of 39 pages; X. *The effect of stimulants on efficiency,* in which alcoholism is especially discussed; and XI. *Morbidity,* covering chief illnesses in relation to various industries, and the corrections and supervision to be recommended.

Each Chapter ends with a valuable set of conclusions which also introduce some new materials. There are numerous tables and graphs, while the work is adeptly headed and sub-headed; the different subjects are well classified. The print of such size and spacing as to be easily legible. Printers' errors are infrequent; repetition is not common; while a thoroughly scientific attitude and fairness is maintained throughout the book.

We could cite omissions such as the "ideal work curve" of Bedford, Leverhulme's "overtime studies," some of the Gilbreths' motion and fatigue studies, and others.

The Index is very inadequate, while on the other hand the Table of Contents is rather too extended and not very useful, since exact pages are not given for the various sub-headings. One is inclined to believe that perhaps disproportionate stress has been placed upon *fatigue* (108 pages) with an additional chapter on *rest periods* of 19 pages, *economic hours of work* 54 pages, *efficiency* 18 pages, *age limits* 17 pages, and *stimulants* 13 pages—all more or less related to *fatigue.* Yet those who consider that all hazards tend toward fatigue will like this arrangement and these inclusions.

Many authorities, boards and reports are cited throughout the work, but there are no reference lists, and no specific bibliography. The work will be found to have collected a considerable amount of valuable and dependable material for industrial managers, teachers and students interested in the field of industrial efficiency from the health viewpoint.

E. R. HAYHURST

Keeping Mentally Fit—*A Guide to Everyday Psychology—By Joseph Jastrow, Ph.D., LL.D. New York: Greenberg,* 1928. 297 pp. Price, $3.50.

This volume consists of a series of daily articles published in the newspapers from October, 1927, to September, 1928, under the direction of the Public Ledger Syndicate.

The author points out that the ways of the mind are good and bad, while mental fitness is a worthy ideal which must be made a practical reality in order to retain our jobs and our content. The need for psychology rests in the fact that meaning is not always found on the surface. The analytical habit of mind makes the psychologist, and attracts minds of similar bent to his findings. There is danger in trying to be all things to all men, claiming dominion and the right to give authoritative advice beyond that which present knowledge justifies and which is often based on past errors. There are many pretenders who have taken the name of psychology in vain, but reaped rich financial rewards through their presumption.

The author was for more than thirty years Professor of Psychology at the University of Wisconsin, and writes from a wide and rich experience. He has a happy art in presenting his ideas and a gift for attractive titles. One will find pretty nearly all questions of everyday life here presented, from complexes to the use of the lipstick.

The articles are grouped under 10

headings. Each one is short and to the point. Everyone will find some puzzle which has bothered him answered in plain language which the non-professional reader can understand.

M. P. RAVENEL

Teachers' Problems in Health Education—*Book I. Teaching How to Get and Use Human Energy—By Thomas D. Wood, M.D., and Marion O. Lerrigo, Ph.D. Bloomington, Ill.: Public School Publishing Co.*, 1928. 128 pp. Price, $0.75.

This book, the first in a series intended primarily to aid in teaching health, deals with the use of big muscles and nutrition in a health education program. The authors promise several of the series, so that none of the important topics of health education will be slighted. When outlined, teachers of the primary and elementary, the junior high and senior high school grades, were had in mind. The book contains much needed basic information for the teacher of health, and offers suggestions for activities that should stimulate the pupils in developing healthy bodies and living healthful lives. This contribution to the too scant field of health education material for teachers will be welcomed.

A. B. TOWSE

Preventive and Corrective Physical Education—*By George T. Stafford. New York: A. S. Barnes & Company*, 1928. 328 pp. Price, $3.00.

This excellent work starts with an introductory argument for a broad and real physical education, rather than a narrow program of athletics only. It emphasizes, too, the need of a thoroughly trained personnel to handle the program. "Nothing has hindered the development of physical education so much as the erroneous idea that because a man has been a professional boxer or a star football player, he will be able to guide the normal growth and organic development of the coming generation."

It also makes a plea for handling cases individually. The idea that corrective gymnastics can be given successfully to massed groups of forty or more is folly.

The pedagogy of preventive and corrective physical education is well presented. It offers thoughts of which all too many practicers of this field of therapy lose sight, namely:

A thorough technical training in physical education is necessary if one is to treat properly the physically defective individual.

In certain cases of malnutrition there is already an overindulgence of physical activity.

One of the objectives of corrective work must be the teaching of self reliance.

The right appeal must be used to secure results.

The need for religiously practicing good hygiene outside of class as well as during class is constantly stressed.

The health of the teacher creates confidence in the pupil.

Teaching health by precept only is a futile task.

In corrective work the pupil is made to understand that his condition is remedied only by the work the pupil performs.

It has also chapters devoted to Physiology of Exercise, Body Mechanics, the Feet, Heart Disturbances, Malnutrition, Constipation, etc., Athletic Injuries, and to other phases of this extensive, complicated, and technical phase of physical education and therapy. Throughout, the author has realized that correction cannot be obtained by exercises alone. Habit, diet, footgear, and various types of electro, thermo, and hydrotherapy are frequently quite as essential.

At the end of each chapter is an extended bibliography of collateral reading.

The book is an excellent treatise for those teachers in physical education who are engaged in corrective work, and for physicians, particularly those largely in contact with adolescent and college youth, who desire more definite information concerning this field of medicine than the ordinary medical curriculum gives. It is well written, printed and illustrated.

CHARLES H. KEENE

The Kahn Test, a Practical Guide—*By R. L. Kahn. Baltimore: Williams & Wilkins,* 1928. 201 pp. Price, $4.00.

As would be expected from the publishers, the general form and appearance of the volume is excellent. The English is clear and concise. The text is presented as a second edition of that part of *Serum Diagnosis of Syphilis by Precipitation* which relates to procedure. The first chapter, which constitutes about one-third of the book, deals with the consideration of the theoretical basis for precipitation tests and a general discussion of the Kahn test. The remaining chapters are devoted to a detailed description of the author's technic. This includes the routine diagnostic test, and the qualitative, presumptive, micro and special procedures for use with serum, as well as the adaptation of the test for spinal fluid. The apparatus required is shown in illustration, and specifications necessary for purchasing are given. The description of the conduct of the work furnishes the minutiae so essential if duplication of results is to be secured. Those conducting the Kahn test will wish to have the volume available for ready reference. RUTH GILBERT

Principles of Sociology—*By Rudolph M. Binder. New York: Prentice-Hall,* 1928. xvi, 609 pp. Price, $5.00.

The author, a professor in New York University, is already well known to students of public health problems through an important treatise, *Health and Social Progress.* He has now produced a general treatise on the principles of sociology. His approach is primarily that of the student of social institutions and cultural development. There is little attention given to geographical, biological, historical, and psychological factors in society and social development, though these influences are touched upon in separate chapters in the first part of the book on "the social population."

The book is in five parts: Social Population, Social Motives, Social Processes, Social Institutions, and Social Aims. The first and the last are of chief interest to students of public health, embracing those portions of the work which treat of biological aspects of social processes and social progress. A special chapter (XXIX) is devoted to The Improvement of Health. The treatment of the biological aspects of society is not, however, as extensive as that in Bushee's *Principles of Sociology* nor as scientific and searching as that in Hankins's *Introduction to the Study of Society.*

The attitude and approach of Professor Binder are those of the social philosopher of the earlier days of sociology, but his materials are more up-to-date than were used by the writers of the last generation. The tone of the book is restrained and conservative, especially on such controversial questions as sex, religion and property.

The work should prove highly congenial to the outlook of the majority of American sociologists and should go far to allay the current conviction that American academic sociology is a disruptive influence in American life and a threat to the morals and well-being of the country. HARRY ELMER BARNES

Old Mother Hubbard and Her New Cupboard—*By Rama V. Bennett. Los Angeles: Los Angeles County Public Health Association,* 1928. 50 pp. Price, $.50.

The famous character of nursery rhymes has been raised to the dignity of custodian of the health of the community, gained by proper nutrition. This attractively prepared volume contains 50 articles on nutrition, with special emphasis on child feeding, all written for the education of the mother, teacher and nurse. The articles first

appeared as weekly contributions in a half-hundred newspapers in Los Angeles County, as one phase of the health education program of the County Tuberculosis Committee and the County Public Health Association. It is a commendable piece of work and shows how an up-and-coming county health department can persuade its editors to educate the public in health. A. B. TOWSE

Growth—*By William Jacob Robbins, Samuel Brody, Albert Gerland Hogan, Clarence Martin Jackson and Charles Wilson Greene. Edited by H. D. Hooker. New Haven: Yale University Press,* 1929. 189 pp. Price, $3.00.

The volume embodies a series of lectures delivered at the University of Missouri under the auspices of the Missouri chapter of the Sigma Xi during the academic year 1925–1926. The five chapters are not in the form of a unified treatment amplified from a single point of view, but each author attempts a fairly comprehensive though fragmentary approach to the subject from a different point of view. The first chapter is largely a definition of growth and delimitation of the problem. It is the only chapter in which the illustrative material is taken from the field of plant life, the remainder of the book dealing almost exclusively with animals, including humans.

In the two following chapters, growth is treated respectively as a statistical process and as a chemical process. The last two chapters are devoted to the morphology and general biology of growth, and the regulating factors in normal and pathological growth.

These several points of view render the book of more general interest than if a single point of view had been maintained, and many workers in the general field of biology should find at least one of the chapters interesting.

Though the chapters are uneven in style and tone, the authors have in many cases succeeded in interweaving some things which are not generally known with others that are matters of fairly general knowledge.

M. P. RAVENEL

Health and Physical Education for Elementary Schools—*By Alonzo Franklin Myers and Ossian Clinton Bird. New York: Doubleday, Doran,* 1928. 342 pp. Price, $1.50.

In their presentation of a modern health education program the authors say:

> We regard health education in the elementary school as including not only formal instruction in health, but also all of the means at the disposal of the school for influencing favorably the habits, attitudes, ideals and knowledge of the child with reference to individual and community health.

To justify this statement they have presented a workable plan, grade by grade, to include the many phases of a well rounded health education program. They have included a chapter on mental hygiene—a commendable point, for too many authors either dodge this subject as outside the pale of an inclusive health program, or because they have not progressed to an appreciation of its importance. The authors who are affiliated with the University of Ohio realize that the success of the public health movement is dependent in large part upon the teaching of this subject in public schools. A. B. TOWSE

The Book of Green Vegetables—*By Mollie Gold and Eleanor Gilbert. New York: Appleton, 1928.* 189 pp. Price, $1.50.

To some who are endeavoring to prepare health meals, green vegetables are only green vegetables; to others they are the foundation of a variety of tasty nutritious dishes. This handy book is a revelation of the variety of ways of preparing green vegetables available throughout the year.

Handbook of Microscopical Technique for Workers in both Animal and Plant Tissues—*Edited by C. E. McClung (with the assistance of 24 Contributors). New York: Hoeber,* 1929. xiv + 495 pp., 43 figs. Price, $8.00.

The text is divided into two parts. The first is for the inexperienced worker who needs guidance in the fundamental principles of making microscopical preparations, including the processes of fixation, dehydration, imbedding, sectioning, mounting, staining, serial sectioning, the preparation of whole mounts and other non-sectioning methods.

The second and more extensive part deals with special methods for the more experienced worker. Special chapters, or parts thereof, deal with microinjection and microdissection by Chambers, with bacteriological methods by Conn, Mallory and Parker, with vital stains by Foot and supravital stains by Sabin, and with botanical microtechnic by Taylor.

Cytological methods are treated by McClung, Allen, Hance, McNabb and Cowdry, embryological methods by McClung and Allen, histological methods as applied to the various tissues by a well selected group of specialists in that field, and protozoölogical methods are presented by Wenrich. A general discussion of fixation and fixatives is given by McClung and Allen, and a very valuable account of stains and staining by McClung. Aniline dyes are dealt with by Conn of the Committee on the Standardization of Stains.

The book is indispensable for all workers using microtechnic in bacteriology, biology, botany, cytology, embryology, histology, pathology, parasitology and zoölogy. It should be in the library of every public health laboratory and laboratory technician. It is the product of the practical experience of eminent specialists and is authoritative. Furthermore, it shows evidence of careful editing and the effort to include minor practical details of manipulation on which the successful preparation of excellent microscopical preparations so often depends. It is quite up to date in the inclusion of recently developed fields and special methods.

CHARLES A. KOFOID

Grundzüge der Hygiene—*By Dr. Max Engling. (2d ed.) Berlin: Urban & Schwarzenberg,* 1929. xiv + 426 pp., 152 figs. Price, 14 marks. Bound, 16.40 marks.

A second edition of this recently published treatise on the elements of hygiene has given opportunity for considerable increase in the illustrations. The sections on communicable diseases and those of medical importance have been expanded. Because of the increased interest among German youth in sport, a section has been added on the hygiene of exercise. The chapter on disinfection has an added section dealing with control of animal plagues, including a full account of delousing methods, and defensive measures against fleas, bedbugs, flies, mosquitoes, and rats and mice. The book is quite up-to-date on the latest German practices in laboratory and sanitary matters. It covers a very wide range of subject matter germane to hygiene and is a valuable addition to the library of the public health officer, technician and the sanitary engineer.

CHARLES A. KOFOID

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

California—By a legislative act of 1927, the State Board of Health was reorganized to become the State Department of Public Health, guided by the State Board of Health, composed of 7 members. The status of communicable disease in California during the past two years has been uniformly satisfactory, according to the 30th biennial report for the period ending June 30, 1928.

Although during the period of the report there was no outbreak of plague among human beings, this disease is a live subject, and "the discovery of large numbers of infected ground squirrels in many counties of the state emphasizes the fact that an endemic focus of this disease exists on the Pacific Coast." It has been four years since a water-borne outbreak of typhoid fever appeared in the state. Nearly all cases are milk-borne or are contracted through contact with cases or carriers. There were but 2.5 deaths per 100,000 population from this disease in 1927. Rabies continues to be a problem, with 376 rabid animals discovered and 1 human death, in 1927.

It is not surprising to find a high tuberculosis rate (140.7 per 100,000), although the trend is downward.

This is the penalty we pay for having an enviable climate. Large numbers of advanced cases of tuberculosis are imported into California each year. About 7 per cent of all tuberculosis deaths in the state annually are of persons who have lived within the state for less than one year, and about 23 per cent are of persons who have lived within the state from one to four years.

The burden of caring for non-resident tuberculosis cases among indigents has fallen particularly heavily upon the counties of southern California.

The report describes the important work done in sanitation during the St. Francis Dam disaster. The flood waters attained a maximum depth of about 125 feet, and traveled, in a solid wall, down San Francisquito Canyon at the rate of 18 miles an hour. As soon as word of the disaster was received, representatives of the department left Los Angeles and San Francisco simultaneously. County departments also participated in the work. Milk supplies were ordered pasteurized; water supplies and sewage disposal plants were safeguarded; and immunization against typhoid fever (3,106 individuals) was instituted. General relief measures were carried on under the direction of the Red Cross, The American Legion, and other local organizations. No cases of communicable diseases as a result of flooded conditions occurred.

Making the Annual Report Worth While—Of three annual reports of health officers which reached the desk of the editor of *Health News* simultaneously, one is almost entirely in the form of a tabulated statement of morbidity and mortality, clinic statistics and financial disbursements. While undoubtedly there are matters of importance hidden in its columns, it forms as interesting reading as a few pages from the dictionary and will be found useful chiefly for purposes of reference and comparison.

In contrast to this report, a health officer of a town in Orange County comments at length on the new milk regulations in his report, indicates the improvements in the supply which have resulted by their enforcement, and discusses in an interesting manner the various clinics held during the year and the results obtained therefrom; he also calls attention to the necessity of holding dogs in quarantine where humans have been bitten, basing his remarks on a

case where the dog was killed too soon and the diagnosis thereby greatly delayed; all this in addition to routine matters which are discussed in a readable manner.

Much the same comment as the last can be made on the report of a health officer of a village in Tioga County. Five closely typewritten pages give a complete outline of his official activities in a conversational style that invites perusal. His remarks on the new milk regulations are worth repeating:

> The application of the new milk code has been the outstanding feature of the past year's work. At first its requirements seemed to be drastic, but as more thought was given, it was found that regardless of its wording it could be reduced to the simple terms "Cleaner and safer milk for the consumer." When one considers the epidemics at Montreal, Canada, and at Lee, Mass., no measure can be too drastic to secure wholesome milk.—*N. Y. Health News,* Feb. 11, 1929.

Dayton, O.—Dayton's 1928 review states that increased emphasis is being given to the need for selling health to the people.

> It is realized that health organizations have very largely covered the field of group health protection. The greatest need now is to have the individual thoroughly acquainted with the means of promoting good health. Individual protection must be practised to make further progress in lengthening the span of life. Every employee of the health department is a salesman of health.

Nurses made 2,466 prenatal calls, the highest number recorded. The Miami Valley Hospital refers prenatal patients from its clinic for visiting nurse follow-up in the home. During the school vacation months, the nurses visited every crippled child in the city to see that proper care was given.

On July 1, the final enforcement of the ordinance requiring that all milk sold in the city be from tuberculin tested cows was begun. Of 2,200 dairies supplying milk to the city, only 80 were required to discontinue sale because of not having complied with the ordinance. A new score card has been devised for food establishments which is said to have increased the efficiency of inspection. Thirty-five per cent of the score is given for proper equipment and 65 per cent for cleanliness measures.

United States Public Health Service—The 57th annual report of the Surgeon General covers the 130th year of the existence of the Service. There were no pandemic outbreaks of any disease, and no country with a modern public health organization was affected by the spread of any of the pestilences which have scourged the world in the past. There was an increase in diphtheria prevalence in practically all European countries, as well as in Australia and certain countries on the Mediterranean coast of Africa. In contrast, there was no general increase in the prevalence of scarlet fever. Infantile paralysis was unusually prevalent in some countries of Europe, particularly Germany, Austria, and Rumania, but did not become epidemic. The necessity for coöperation among the nations of the world in preventing the spread of diseases dangerous to the public health has been more widely recognized during recent years than formerly.

During the calendar year 1927, health conditions were relatively good in the United States, and preliminary figures indicate that the general death rate was the lowest ever recorded. There was, however, an increase in the prevalence of diphtheria which continued throughout the year, and during the first few months of 1928.

> Again the United States has the unenviable distinction of reporting more cases of smallpox during the year than any other country in the world from which reports are received, except India. It is difficult to understand why this condition is allowed to continue year after year. A large percentage of the property in this country is insured against loss by fire, and

a man who fails to provide for his family by taking out life insurance is censured; yet when smallpox is introduced into a community in the United States, it usually finds many victims who have never been vaccinated and others who have not been vaccinated for many years. Nearly 34,000 cases of smallpox in the United States in the calendar year 1927 testify to the neglect of the people to utilize vaccination, the known means of preventing this disease.

Tuberculosis had a new low record. The death rate in 41 states of 77.3 was 7 per cent lower than the rate in these States for 1926, and 8 per cent lower than for 1925. The decline of typhoid fever affords a striking example of the results of practical application of the principles of modern sanitary science.

A somewhat detailed account of investigations of public health problems deserves careful study. Among the important recommendations of the report is one relating to the collection of sickness reports. Legal authority has existed for more than 35 years for the collection by the Service of information relating to the prevalence of disease, but there is no specific appropriation for the purpose. The establishment of a registration area for diseases dangerous to the public health would do much to secure uniform, trustworthy, and prompt reports, and it is recommended that an appropriation be granted for this purpose.

CARE OF THE MOUTH AND TEETH. By Harvey J. Burkhart, D.D.S. New York: Funk & Wagnalls, 1928. Price per copy, $.30.

AN APPRAISAL OF PUBLIC HEALTH ACTIVITIES IN DENVER, COLO. Including the Activities of Official and Voluntary Agencies for the year 1927. By James Wallace, M.D., for the Committee on Administrative Practice of the American Public Health Association. New York: A. P. H. A., 1928. 102 pp. Price, $.50.

YOUR TEETH. By Charles I. Stoloff. New York: Dutton, 1929. 224 pp. Price, $2.50.

HEALTH AND PHYSICAL EDUCATION. By A. F. Myers and O. C. Bird. New York: Doubleday, Doran, 1928. 342 pp. Price, $1.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Women in Industry—The ability of women to do hard work in industry is discussed from experience in Great Britain. The plea is made for better midwifery to prevent postpartum disabilities which unfit women for industrial positions.

ADAMSON, R. H. B. The Health of Women and Girls in Relation to Industry. J. State Med. 37, 2: 107 (Feb.), 1929.

Non-Official Health Agency Functions—In addition to the accepted investigational, demonstrational and educational functions of the voluntary agency, the author raises the question whether private agencies may not carry out other health services, always under guaranteed official control.

ARMSTRONG, D. B. The Field and Functions of the Private Health Organization. New England J. Med. 200, 8: 387 (Feb. 21), 1929.

Nutrition and Pneumonia—In a study conducted in a child-caring institution, nutrition (in children under 5) appeared to bear no relation to the incidence of pneumonia. Rickets, too, did not predispose to pneumonia. Nutritionists please take notice!

BARENBERG, L. H., et al. The Relationship of Nutrition to Pneumonia in Infancy and Childhood. J. A. M. A. 92, 6: 440 (Feb. 9), 1929.

The Laboratory's Contribution to Longevity—An Irishman's search for all the ways in which bacteriology has added to the expectation of life gathers up every scrap of credit possible and lays it at the door of the laboratory. The paper is really a plea for better laboratory service in Ireland, but one would never guess it at the beginning.

BIGGER, J. W. The Expectation of Life and the Bacteriological Laboratory. J. State Med. 37, 2: 76 (Feb.), 1929.

Industrial Morbidity Experience—Respiratory diseases were the cause of 41.8 per cent of claims for the industrial illness benefits; digestion diseases, 13.7 per cent; and non-industrial accidents, 10 per cent; (virtually two-thirds) of the benefits paid by associations reporting to the U. S. Public Health Service. The incidence rates increased during the years 1921 to 1927. The study presents many other interesting findings.

BRUNDAGE, D. K. Sickness among Industrial Employees. Pub. Health Rep. 44, 8: 387 (Feb. 22), 1929.

Morbidity Survey—A sickness survey in rural New York made by the State Department of Health demonstrated the numerically unimportant position of the reportable diseases, and suggested that more attention be paid by health officials to the non-reportable conditions.

DE PORTE, J. V. Sickness in Rural New York. J. A. M. A. 92, 7: 522 (Feb. 16), 1929.

Sensitization by T–A Mixture—Persons immunized by toxin-antitoxin mixture were sensitized to horse serum in 74 per cent of cases, whereas of untreated persons only 18 per cent were found sensitized. The reactions in the treated group were more severe than in the untreated. The use of toxoid or goat antitoxin is urged.

GORDON, J. E., and GRESWELL, S. M. To What Extent Do Toxin-Antitoxin Mixtures Sensitize to Therapeutic Serum? J. Prev. Med. 3, 1: 21 (Jan.), 1929.

School Ventilation—Another study has been made indicating a greater amount of respiratory illness in mechanically ventilated school rooms than in those with window ventilation. This

study confirms the findings of New York Commission on Ventilation. How many more times will these findings have to be confirmed before our school ventilation methods become more civilized?

GREENBURG, L. A Study of the Relationship between Type of Ventilation and Respiratory Illness in Certain Schools in New Haven, Connecticut. Pub. Health Rep. 44, 6: 285 (Feb. 8), 1929.

Results of Breast Feeding—In a study of 383 elementary school children, those artificially fed were found inferior both physically and mentally to the breast-fed; they were more poorly nourished, more susceptible to disease, slower in mental development. This seems "too good to be true."

HOEFER, C., and HARDY, M. D. Later Development of Breast Fed and Artificially Fed Infants. J. A. M. A. 92, 8: 615 (Feb. 23), 1929.

Parasitism in Philadelphia—Intestinal parasitism may be found frequently in clinic patients in American cities, the condition being by no means confined to tropical regions. In this study numerous infections with amebas and giardia were detected.

DE RIVAS, D., and FIFE, C. A. Intestinal Parasitism in Philadelphia. J. A. M. A. 92, 8: 624 (Feb. 23), 1929.

Respiratory Infections and Rheumatism—Evidence is offered which indicates close association between infections of the upper respiratory tract and rheumatic fever. Care in a convalescent home does not reduce infections after the child is returned to his home.

MCCULLOCH, H., and IRVINE-JONES, E. I. M. The Rôle of Infection in Rheumatic Children. Am. J. Dis. Child. 37, 2: 252 (Feb.), 1929.

Treatment of Market Wastes—The method adopted in Birmingham, England, for transforming wastes from meat markets, slaughterhouses, and vegetable markets into salable fertilizer and animal feeds is described in detail.

WEAVER, W. The Treatment of Organic Waste. J. Roy. San. Inst. 49, 8: 478 (Feb.), 1929.

Vitamin Content of Milk—Human and cow's milk contain about the same amounts of vitamin A, the former only about half as much vitamin B as the latter. Both are deficient in the antirachitic factor. The vitamins in cow's milk are apt to be dissipated by adverse treatment. The effects of a vitamin deficient diet are discussed.

MACY, I. G., and OUTHOUSE, J. The Vitamin Content of Milk Used in Infant Feeding. Am. J. Dis. Child. 37, 2: 379 (Feb.), 1929.

Scarlet Fever Carriers—In a study of 1,011 cases of scarlet fever coming from 343 families, it was found that return cases occurred when convalescents were sent home with hemolytic streptococci demonstrable in the throat. Hemolytic streptococci survive long after the convalescent period in about 60 per cent of the patients.

MORIWAKI, G. The Relationship of Hemolytic Streptococci to the Spread of Scarlet Fever. J. Infect. Dis. 3, 1: 1 (Jan.), 1929.

Spray Painting Hazards—This paper describes the booths and ventilation apparatus used in spraying lacquers on automobile bodies.

VOGT, J. H. Ventilation in Connection with Applying Coating and Finishing Materials to Automobiles by the Use of Atomizers and Compressed Air. Indust. Hyg. Bull. (N. Y. Dept. of Labor) 5, 8: 29 (Feb.), 1929.

NEWS FROM THE FIELD

TULAREMIA IN RUSSIA

TULAREMIA, hitherto thought to exist only in the United States and Japan, has been found to exist in Asiatic Russia. *B. tularense,* the causative organism of tularemia transmitted to humans by rabbits, was discovered in tissue received from the Sanitary Bacteriological Institute of Sverdlovsk (Ekaterinburg) in the Ural region of Asiatic Russia.

EPIDEMIC OF SMALLPOX IN BOMBAY

GREAT alarm has been felt in Bombay on account of a severe outbreak of smallpox, which has caused 247 deaths out of 500 cases since January 1. One hundred new cases were reported the last week in February. Six thousand persons have been vaccinated since the first of the year in the 20 vaccination stations established throughout the city.

NEW YORK LEAGUE FOR THE HARD OF HEARING HAS NEW HOME

THE New York League for the Hard of Hearing has moved its offices to the 11th floor of the Grand Central Palace. The Grand Central Palace, famed for 17 years as housing many great exhibitions, has been purchased and converted into an office building. Social agencies have been particularly welcomed.

CONVENTION OF THE AMERICAN PHYSICAL EDUCATION ASSOCIATION

THE convention of the American Physical Education Association, which takes place at Yale University, New Haven, Conn., April 17–20, will be comprised of delegates from all over the United States. The convention will be addressed by prominent authorities in the field of physical education, the general topic being, "Modern Trends in Physical Education."

INCREASE IN PREVALENCE OF SPINAL MENINGITIS

ON March 11, in its weekly report on communicable diseases, the U. S. Public Health Service announced an increase in the prevalence of cerebrospinal meningitis throughout the United States. For the week of February 10, 251 cases were reported by 45 states as contrasted with 94 cases reported for the same week of 1928. Ninety-seven cities of more than 31 million population reported 143 cases the same week this year as against 42 cases during the same period last year.

SANITARY SURVEY OF GREECE

THE Government of Greece has requested the League of Nations to make a study of sanitary and health needs of her population and make recommendations for a national health service. A commission appointed by the Health Organization of the League started work in Athens on February 15. L. L. Lumsden, M.D., of the U. S. Pubice Health Service, and Haven Emerson, M.D., of New York, were elected to serve as members of this commission. Owing to injuries received in an automobile accident, however, Dr. Lumsden was unable to go, and A. J. McLaughlin, M.D., of the U. S. Public Health Service, was chosen to take his place.

DEATH OF PROFESSOR PIRQUET

BARON Clements Pirquet, noted scientist and professor at the University of Vienna since 1911, and his wife died of coal gas poisoning at their home in Vienna, on February 28.

Professor Pirquet, who was 55 years old, was well known in Europe and the United States for his treatment of crippled children, for which purpose he established a clinic in Vienna, and later a model of this was founded here. His most important discovery was the "Pirquet Reaction" method of inoculation.

Professor Pirquet was also the author of several valuable books, *Allergie, Cutaneous Tuberculin Tests,* and *New System of Feeding.*

Because of his international reputation Professor Pirquet was mentioned as a possible candidate for the presidency of the Austrian Republic at the elections last November.

CONFERENCE ON PUBLIC HEALTH OF THE A. M. A.

THE following were representatives of the American Public Health Association at the Conference on Public Health of the American Medical Association, in Chicago, Ill., March 29–30: George W. Fuller, *President,* A. P. H. A., M. P. Ravenel, M.D., Louis I. Harris, M.D., W. F. Walker, D.P.H., Henry F. Vaughan, D.P.H., John E. Monger, M.D., Professor E. O. Jordan, and Homer N. Calver.

DELTA OMEGA LECTURE

THE first Delta Omega lecture was given at the Yale School of Medicine on March 8, by James A. Doull, M.D. The subject of Dr. Doull's discourse was, "Factors in the Selectivity of Diphtheria and Scarlet Fever." Professor C.-E. A. Winslow presided at the meeting, which was attended by many from the medical school and department of public health.

The second of these lectures will be given at the Massachusetts Institute of Technology on April 12, by George T. Palmer, D.P.H., on the School Health Study of the American Child Health Association.

SECOND INTERNATIONAL CONGRESS ON MALARIA

THE French Ambassador, Paul Claudel, has announced that the second international congress on malaria will be held at Algiers in May, 1930. This occasion will celebrate the fiftieth anniversary of the discovery of the malaria parasite by M. A. Laveran in Algeria, and the centennial of French Algeria as well. Representatives from many nations will convene at this time with the purpose of controlling the existing prevalence of malaria.

PERSONALS

DR. HENRY P. WALCOTT, for over 25 years president of the Massachusetts General Hospital, resigned his position on February 6 and was made Honorary President of that institution. Dr. Walcott has devoted a great part of his 91 years to public health interests. During his career he has been president of the Massachusetts Medical Society; first chairman of the Massachusetts Board of Health; chairman of the Metropolitan Water Commission; Fellow of the Harvard Corporation. He is an Honorary Fellow of the American Public Health Association.

ISAAC D. RAWLINGS, M.D., Director of Public Health of Illinois for eight years, resigned this position February 14 to become First Assistant Health Commissioner of the city of Chicago. Before his appointment as State Director of Public Health in 1921, Dr. Rawlings was affiliated with the Chicago Health Department for more than 20 years.

WILLIAM DE KLEINE, M.D., has become medical assistant to the vice-chairman of American National Red Cross, and will carry on the growing program of the Red Cross in health education.

S. E. FROST has taken charge of publicity for Philadelphia Health Council.

PHILIP P. JACOBS, Ph.D., as director of Publications and Extension Service, will be responsible for periodical publications, the training of workers, and vocational service of the National Tuberculosis Association. Elizabeth Cole and Eleanor B. Conklin will be assistants.

H. E. KLEINSCHMIDT, M.D., as director of the newly formed Health Education Service of the National Tuberculosis Association, will be responsible for all adult health education activities, lay and medical. A. Scheffer, Jr., will be assistant.

EDWIN C. LANIGAN is chief of public health education, New Jersey Department of Health.

RUTH WARE is director of health education, Y. W. C. A., Syracuse, N. Y.

HELENA L. WILLIAMS, of National Tuberculosis Association publicity staff, is now with Wales Advertising Co.

DR. W. A. CLAXTON, formerly Health Officer of Miami, Fla., was appointed to take the position of Health Officer of Morgan County, Ill.

DR. W. L. HOLT, Portland, Me., has been appointed Director of the Division of Communicable Diseases and Social Hygiene of the State Department of Health.

DR. CHARLES H. HALLIDAY, Chief Epidemiologist of the California State Department of Health, has been appointed Deputy State Health Officer of Anne Arundel County, Md.

GUSTAVE WINDESHEIM, M.D., Fellow, A. P. H. A., was reëlected President of the Wisconsin State Board of Health at the annual meeting.

DR. ROBERT S. BREED and PROFESSOR JAMES D. BREW have been appointed consultants to the N. Y. State Department of Health on Dairy Sanitation. Dr. Breed, who is chief in research at the N. Y. State Agricultural Experiment Station, was chairman of the section on dairy bacteriology at the World's Dairy Congress last June. James D. Brew, Professor of Dairy Industry Extension at the College of Agriculture, Cornell University, was a member of the committee which prepared the revision of the N. Y. State Milk Code, effective last July.

C. A. HARPER, M.D., Fellow, A. P. H. A., continues in his twenty-sixth year as State Health Officer of Wisconsin.

The Mortality Trend in the Industrial Population*

LOUIS I. DUBLIN, PH. D., FELLOW A. P. H. A.

Statistician, Metropolitan Life Insurance Company, New York, N. Y.

IN THIS paper is presented a summary of a report just completed on the mortality experience among 3¼ million white male wage earners insured in the Industrial Department of the Metropolitan Life Insurance Company. The study covered the 3-year period 1922 to 1924 inclusive, and is an exact parallel of one covering the 3-year period 1911 to 1913. Taken in conjunction with this earlier work, our present investigation makes available a picture of mortality probably unsurpassed in detail among American wage earners during the years when the movement for better industrial hygiene was being widely extended. It should be kept in mind that the industrial policy holders who formed the basis of the study consist of people in the United States and Canada who earn their livelihood in our manufacturing plants, mines, transportation industries and other mechanical pursuits. They constitute a fairly homogeneous social and economic group which may be described as the urban wage earning population.

The adult males of this class have a higher mortality and diminished longevity than those in other forms of employment. As is shown in Table I, the mortality rate for the group of insured males is higher than that of all males living in the U. S. Registration States in every age period from 25 to 64 years.

Curiously enough, the mortality rate of the insured group, at all ages combined, is lower than that of males in the registration states, being 11.8 and 13.8 per 1,000 respectively. This is due to lower mortality in the first age group—15 to 24 years—and in the last—65

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

DEATH RATES PER 100,000 FOR ALL CAUSES OF DEATH
AGES 15 YEARS AND OVER
White Males
1923

Years of Age	15 and over	15 to 24	25 to 34	35 to 44	45 to 54	55 to 64	65 and over
United States Registration States	1,384.5	363.8	457.7	717.4	1,207.4	2,527.8	8,304.6
Metropolitan Industrial Dept.	1,183.5	347.2	556.1	946.6	1,725.4	3,385.3	7,574.7
Per Cent Insured of Population Death Rates	85.5	95.4	121.5	131.9	142.9	133.9	91.2

years and over. At age 25, the mortality rate of the insured is already higher and remains so up to age 64, increasing progressively from age 25 to 54 years. In the age period 45 to 54 years, the death rate for the insured exceeds that for the general population group by 43 per cent. In the succeeding age period—55 to 64 years—the rate is 34 per cent higher. These rates reflect the results of industrial exposure. In the beginning, the group of policy holders is in its best physical condition and has a lower mortality rate than the general population. At age 25, the situation changes; and thereafter, largely we believe as a result of industrial hazards, the mortality rate is heavier than that of the general male population. The last age period, where the insured again make a more favorable showing, is not reliable because most of our industrial policies terminate at age 74. It therefore follows that the average age of policy holders in the class 65 years of age and over is lower than that of the corresponding population group; and consequently, other things being equal, one would expect their mortality rate to be lower.

The effects of industry are also clearly revealed in the differential death rates for males and females of the same economic class. Comparing the death rates given in Table II for male policy holders and for their wives and sisters as represented by our female industrial policy holders, we find some striking differences. After age 10, the mortality rates for males are consistently higher than for females, with the single exception of the age period 15 to 24 years. Since the industrialization of women is then at its height, the question of the

TABLE II

DEATH RATES PER 100,000 FOR ALL CAUSES OF DEATH
AGES 10 YEARS AND OVER
METROPOLITAN LIFE INSURANCE COMPANY
INDUSTRIAL DEPARTMENT
1923

Years of Age	10 to 14	15 to 24	25 to 34	35 to 44	45 to 54	55 to 64	65 and over
White Males	198.6	347.2	556.1	946.6	1,725.4	3,385.3	7,574.7
White Females	162.4	353.3	491.9	677.9	1,188.0	2,576.1	6,726.7
Per Cent Male of Female	122.3	98.3	113.1	139.6	145.2	131.4	112.6

relative susceptibility of men and of women to the exactions of industry upon their health is definitely raised. After this age, the large majority of these women become housewives, and we notice a much lower rate of mortality for them in each succeeding age period than for men. This, we think, is largely traceable to the absence of industrial hazards in the life of most women.

Even more marked differences suggestive of the effects of industrial exposures are found when the mortality of industrial males is compared with that of persons who are for the most part engaged in non-hazardous pursuits. We may take, for this comparison, white male policy holders insured in the ordinary department of the Metropolitan Life Insurance Company, composed mainly of the clerical, professional, and commercial classes. Agricultural workers and the better paid mechanics are also represented in fairly large numbers. Age for age considered, the mortality rates for the industrial group run from one and one-half times to more than double the rates for those in the ordinary department. This is shown in Table III.

TABLE III

DEATH RATES PER 100,000 BY SPECIFIED AGE GROUPS FOR ALL CAUSES OF DEATH, 1923
REGULAR ORDINARY DEPARTMENT PREMIUM-PAYING BUSINESS (TOTAL MALES)
COMPARED WITH INDUSTRIAL DEPARTMENT PREMIUM-PAYING BUSINESS (WHITE MALES)

Years of Age	20 and over	20 to 24	25 to 34	35 to 44	45 to 54	55 to 64	65 and over
Industrial Males	1,404.1	400.6	556.1	946.6	1,725.4	3,385.3	7,574.7
Ordinary Males	550.0	255.2	268.4	422.0	790.1	1,868.0	5,604.1
Per Cent Industrial of Ordinary	255.3	157.0	207.2	224.3	218.4	181.2	135.2

In terms of life expectation, the severer status of the industrial worker is equally impressive. The industrial worker at age 20, when he begins his career, has an expectation of life of 42 years; or in other words he may expect to reach 62. The 20-year old worker engaged in non-hazardous occupations, however, may expect to attain age 69, or 7 years additional. Industrial workers are at a disadvantage in each succeeding period; at age 30 the difference is 6.6 years, at age 50, 4.2 years, and at age 70, 1.3 years, always in favor of the non-industrial group.

The above comparisons between the death rates of various groups —males insured in the industrial department of the Metropolitan, males of the registration states, males insured in the ordinary branch of the Metropolitan, and females of the wage earning class—show clearly the influence of industrial environment on mortality rates and life expectation. The difference in the mortality rates for these groups gives a rough measure of the tax which industrial work exacts,

and reflects the hazards to which workers are exposed. Other items obviously account for a part of the disparity in these figures. Heredity and innate differences play some part, but probably the most important factors are the conditions incidental to industrial employment including deleterious dusts, excessive fatigue, bad posture, crowded work rooms, dampness, extreme changes of temperature and sometimes specific occupational poisoning, to which industrial workers are so frequently exposed.

The health picture of the industrial worker is, however, far from discouraging when we consider the vast improvement which has taken place in recent years. Between 1912 and 1923 the death rate for our industrial group has declined from 1,621.7 per 100,000 to 1,183.5 per 100,000. Not only has there been a total decline of 27 per cent, but a substantial decline in the death rate has characterized every age group. On account of this reduced mortality, almost 14,000 fewer deaths have occurred among the 3¼ million policy holders in the single year of 1923 than would have taken place had the mortality rates of 1912 prevailed. This amounts in terms of life expectation to an average increase of 5 years for each industrial worker at age 20; and there has been some increase in longevity at every age period. The greatest reduction in mortality has taken place in the important working ages 25 to 34 and 35 to 44, when the rates declined 43.1 and 41.2 per cent respectively. Less progress is recorded after age 55, the decline amounting to only 16.4 per cent in the age period 55 to 64 years.

Turning now to a consideration of the specific diseases causing mortality among our working population, we find that almost every cause of death has shared in the highly gratifying downward trend of mortality.

Tuberculosis of the respiratory system, which in 1912 was the chief cause of death, has shown a very great improvement, the death rate declining from 319.9 per 100,000 in 1912 to 149.7 in 1923, a fall of 53.2 per cent. As a result, tuberculosis is now superseded by heart disease as the leading cause of death. Workers 25 to 34 years of age and 35 to 44 years were the most favorably affected, the decreases amounting to 60.2 and 62.6 per cent respectively. Nephritis has shown a significant though a smaller decrease of 38.0 per cent, the rates declining from 178.1 for all ages in 1912 to 110.5 in 1923. The mortality rate of this disease showed the greatest decline in the 35 to 44 age period where it went down 55.7 per cent. Mortality from pneumonia also showed a substantial reduction of 26 per cent, the rate in 1923 being only 92.5 per 100,000. The younger workers en-

joyed the greatest decline, the reduction amounting to 42.4 and 35.2 per cent respectively in the age periods 25 to 34 and 35 to 44. The fatal accident rate was reduced from 140.6 in 1912 to 121.2 in 1923, a decline of 13.8 per cent. Organic diseases of the heart showed little change at all ages. The death rate declined 7.5 per cent, or from 203.9 per 100,000 to 188.7. In the age period 35 to 44, however, the reduction amounted to 33.5 per cent.

Some of the lesser causes of death display a marked diminution, notably typhoid fever, cirrhosis of the liver and suicide, with decreases of 72.2, 65.4 and 42.2 per cent respectively. The effects of better industrial hygiene are clearly seen in the 50 per cent decline in the death rate from chronic lead poisoning, a disease almost exclusively occupational in origin.

Several exceptions to the general downward trend of mortality are to be noted. Cancer has increased in frequency, the death rate rising from 77.6 per 100,000 in 1912 to 94.9 in 1923, a rise of 22.3 per cent. In the important age periods 45 to 54 and 55 to 64, the rates increased 15.5 per cent and 30.6 per cent respectively. Influenza went up 157 per cent and automobile accidents almost 500 per cent at all ages. Diabetes and homicides registered increases, 13 and 18 per cent respectively for all ages. Cancer, influenza and automobile accidents increased at every age period; diabetes at every period after age 45; and homicides at every period except the 45 to 54 and 55 to 64.

TABLE IV

PER CENT DECLINE IN DEATH RATES AMONG WHITE MALES AND WHITE FEMALES INSURED IN INDUSTRIAL DEPARTMENT AND AMONG WHITE MALES OF THE REGISTRATION STATES OF 1910

	Metropolitan Life Insurance Company 1912 to 1923		Registration States 1911 to 1923
Age Group Years	White Males Per Cent	White Females Per Cent	White Males Per Cent
15 and older	27.0	21.1	3.5
15–24	26.0	21.1	19.3
25–34	43.1	27.5	29.0
35–44	41.2	28.2	23.2
45–54	26.3	17.5	15.7
55–64	16.4	13.7	6.1
65 years and older	13.4	12.1	+ 3.6

Those who are concerned with the health of the working population will be especially interested to observe that the death rate at every age has declined more rapidly for the industrial group than for others.

Table IV shows the percentage of decline in mortality of white males insured in our industrial department as compared with insured

white females and white males of the general population (U. S. Registration States of 1910).

Age for age considered, the decline in the death rates for our insured group has been from 7 to 18 per cent greater than the decline for males of the registration states; and from 1 to 16 per cent greater than for females of the industrial population. The greatest gain for all classes has been at the ages 25 to 34 and 35 to 44 years; and at these ages also the rate of decline for industrial males exceeds by the greatest margin the decline in the rates of the other classes. It would be very instructive if we could make similar comparisons between the trend in the death rates for individual causes of death for males of the registration states and for males insured in our industrial department. Unfortunately, the data necessary are not available. However, our figures, although incomplete, indicate that the decline in mortality among industrial males has been more rapid for all of the more important causes of death. This fact has been conclusively shown for tuberculosis in a recent study[1] on the declining tuberculosis death rate where it is pointed out that the maximum decline in the death rate from tuberculosis among industrial males between the years 1911 and 1925 occurred at the ages between 20 and 45 years and that at these ages the rate of decline was about 20 per cent greater among industrial males than among males in the general population.

It would be of the utmost value to our discussion if it were possible to present the facts for the trend of mortality among men engaged in specific occupations. We should then be able to learn whether all occupations were sharing in the improved conditions; what preventive measures had been productive of the greatest good; and where there was the greatest need for intensive future efforts. Incredible though it may seem, the number of occupations for which we have death rates covering a period of years in the United States is very small and the data do not lend themselves to ready interpretation. We did not have for our study the number of insured in each occupation; and for that reason, we cannot present death rates by occupation. We were, therefore, compelled to use the method of proportionate mortality, that is, to find out for each occupation the part that any cause of death played in the total mortality with due regard to age. While not as sensitive a measure as actual death rates, this method affords a fairly reliable indication of what the actual death rates for each cause would show. It is not feasible to present here the many instructive findings of this analysis. The facts for tuberculosis, however, are outstanding and are of especial interest to industrial hygienists.

Seventy-two occupational classes were investigated. Of these, all but 6 showed a lower percentage of deaths from tuberculosis in the period 1922 to 1924 than in 1911 to 1913. The occupations with the highest proportion of deaths from this cause were, in order: miners, underground—other than coal miners; pottery workers; stone cutters; waiters and hotel servants; cutlers and grinders; cigar makers and tobacco workers; laundry workers; compositors, printers, and pressmen; brass foundry workers; barbers and hair dressers; glass workers; and the clerical workers. There has been a decline in the percentage of deaths from tuberculosis for each of these occupations, except the miners (other than coal miners), since 1911–1913. Data are not available for individual groups of metal miners, such as gold and silver, lead and zinc, iron, etc.; but as a group, metal miners have shown, in more recent years, a higher ratio of deaths from tuberculosis than they did a decade or more ago. The increase is so slight that it is entirely possible that the actual tuberculosis death rate has decreased in this group, also. The apparent higher proportion of deaths from tuberculosis among miners may well be the result of greater reductions for the other major causes of death.

What factors have brought about this vast improvement in the health and longevity of industrial workers? Surely among the many causes must be included the wide expansion of workmen's compensation, preventive industrial medicine, the safety movement, the reduction in the hours of labor, elimination of the sweat-shop, better plant sanitation, the wider education of the workers regarding the dangers inherent in certain occupations, and the more intelligent care now taken to safeguard the health of workers, as contributory to this gratifying result. But even more important has been the improved standard of living which the increased prosperity of the American wage earner has provided. The outlook for the future is bright indeed. There is every reason to believe that the continuation and expansion of health activities in industry, noticeable everywhere, will result in further reductions in mortality. The trend in the death rate according to our recent figures is still downward. It is not unreasonable to expect, therefore, that in the not far distant future the mortality rates of industrial workers will approach, if they do not quite equal, those of the more favored classes of the population.

Vitamins as Factors in Health and in Food Values II*

IN OUR report of last year,[1] attention was called to the fact that the so-called vitamin B had been shown to be of multiple nature, this one term having covered at least two nutritionally essential substances, one the long recognized antineuritic vitamin, the other more heat-stable and possessing what Goldberger has designated as a pellagra preventing property. While these "anti-disease" properties serve as convenient means of distinguishing the two factors and are, at least in some regions, also of very great intrinsic importance to the public health, yet it is no less important to recognize with equal clearness that both the substances perform essential functions in normal nutrition as well.

So recent is this differentiation of the former vitamin B that many of its phases remain to be worked out, so that their discussion at present would be more or less premature. Even terminology is still under discussion.

Miss Smith[2] has conveniently summarized much of the evidence for the existence of at least two essential factors, and the various designations which have been applied to them; and at our last meeting Dr. Eddy[3] reported quite fully upon certain phases of this interesting development of our knowledge of the vitamins, with special reference to recent progress in the study of the chemistry of the antineuritic substance, and the experimental differentiation of the other factor or factors through the current research work of himself and his associates.

These summaries and discussions are so recent and so readily available that it seems best to forego the traversing of the same ground in this report; but rather to devote the limited space available to the bearings of this new development upon the particular aspect of the matter with which this committee as such is immediately concerned, that is, these vitamins as factors in food values and in health.

In the matter of food values, it is plain that in future we must deal with two (or more) factors in considering that part of our nutritive requirement which in the past has been covered by the one term "vitamin B." How quickly and completely all statements, which in

* Report of the Committee on Nutritional Problems presented to the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

the past have been made in terms of vitamin B, now can and should be dismissed from our minds is a question of judgment and temperament which it is not our present purpose to debate. Much could be said, on the one hand, in favor of the prompt rejection of whatever is contaminated with misconception; and, on the other hand, in favor of conserving the results of the very considerable amount of good work which has already been recorded upon the vitamin B values of foods in so far as this can be done by well reasoned reinterpretation of soundly determined experimental facts.

Whatever position the individual student or teacher of food values may take in this connection, it is certain that references to the vitamin B of the past as a factor in food values cannot be expunged from the literature, and the question of their meaning will continue to be pertinent for some time to come.

Such tests for vitamin B values as have in the past been made by means of the prevention or cure of polyneuritis in pigeons are presumably indications of the antineuritic values of the materials thus tested.

But most workers have felt that the rat growth method yielded more uniform results, and so it has been more generally used in examining foods for vitamin B values. Foods which have been found by this method to have high vitamin B value, as the term has been understood in the past, may now be understood to be valuable sources of both the nutritional essentials now recognized as the antineuritic and antipellagric factors (since both are essential to growth); and such an item in our knowledge of food values seems even more significant now than before.

As both the antineuritic and antipellagric factors are essential to growth, paucity of either one would result in giving a food a low vitamin B value as hitherto tested by the rat growth method. Hence foods which have been reported as of low vitamin B value on the basis of such tests should now be tested quantitatively for each of the two factors separately; for such a food may be relatively richer in one than in the other.

This may also be true in the case of a food which is a good source of both. In fact, cases of outstanding excellence in each of the two directions have already been established. Whole wheat (and doubtless this will be found to be true of other cereals also) has been shown to be especially rich in antineuritic, and milk especially rich in antipellagric value. Each of these important foods is a good source of both factors, yet when eaten together they gain still further in nutritive value through their supplementary relationship to each other.

THE PELLAGRA PROBLEM

A more complicated situation confronts us when we turn to the consideration of the precise relationship of the antipellagric factor (the heat stable nutritional essential of the former vitamin B) to the theoretical and practical problem of the prevention of pellagra. We recognize the appropriateness of the term antipellagric in the sense that this factor undoubtedly tends to prevent the development of pellagra-like symptoms in experimental animals; but it seems probable that other substances (not necessarily closely related to this one in their chemical natures or normal nutritional functions) may also help to keep the body in a pellagra resisting state of health.

In this case more than one factor may be antipellagric, and no one substance may hold the same all-controlling relation to pellagra that the antineuritic substance appears to bear to beriberi.

Much evidence seems to support this view. In the first place, pellagra may not be so purely a deficiency disease as beriberi and scurvy now appear to be.

Jobling and others[4] have presented evidence which, while professedly somewhat tentative, seems much too significant to be ignored, to the effect that there is involved in pellagra an infectious agent which is able to establish itself in the human organism when the latter is malnourished through subsistence upon unbalanced diet.

Such a view of pellagra, as both an infectious and a nutritional disease, would place it in a category similar to that to which sprue is ordinarily assigned.

Tuberculosis is also a disease in which both infection and nutrition are involved, though here still other factors are known to be involved also, and the case *seems* distinctly different because the infectious agent is now well known. It is possible, however, that if we knew both cases better, the comparison of these two diseases might seem much more natural; and McCollum has advanced the idea that the all too frequent shortage of calcium and vitamin A in the diet is a common cause in rendering the body susceptible to either tuberculosis or pellagra, as the case may be.

A perhaps more familiar nutritional theory[5] has associated pellagra (or susceptibility to pellagra) with inadequacy in the kind or amount of food protein, such as to lead to a shortage of one or more of the essential amino acids which the proteins supply; and a few years ago some experimental evidence was reported from England which seemed to link the prevention and cure of pellagra-like conditions with the definite amino acid, tryptophan. So far as we know, this work has neither been confirmed nor explicitly refuted.

Important new evidence, however, now focuses our attention upon other nutritional factors.

The work of Goldberger and his associates[6] of the U. S. Public Health Service, in demonstrating that the heat-stable factor of the former vitamin B has the property of preventing a pellagra-like condition in the rat, has already been mentioned.

Simultaneously, Underhill and Mendel have shown that there is also a fat-soluble substance which prevents the development of a pellagra-like condition in the dog.[7]

In their second and very complete paper, Underhill and Mendel give full accounts of numerous experiments in which butter fat, egg yolk, carrots, or crystallized carotin has prevented or cured the pellagra-like condition of nutritional deficiency disease which Chittenden and Underhill discovered in 1917. We can make no better use of the necessarily limited time and space available for the consideration of this important work of Underhill and Mendel than to quote the summary with which they conclude their paper:

> When butter fat is fed to dogs suffering from the deficiency disease described by Chittenden and Underhill in 1917, these animals are quickly restored to a normal condition and may be maintained in health for prolonged periods.
>
> Under similar circumstances cod liver oil, known to contain active fat-soluble vitamin A, fails to restore these diseased dogs. Evidently this vitamin is not the potent factor in butter fat.
>
> The effective factor in butter fat is apparently quite labile for the potency is diminished by maintaining in cold storage during a period of 9 to 11 months.
>
> The presence of the potent factor in butter fat is associated with the color of the butter. As the color decreases the potency is diminished.
>
> Egg yolk contains the effective factor but is apparently less potent than butter fat.
>
> Boiled unpeeled carrots are even more effective in curative properties than is butter fat.
>
> Lard extracts the potent agent from carrots.
>
> It would appear that there is a direct relationship between the presence of carotinoids in the substances tested and the potent factor.
>
> Crystallized carotin in relatively small doses is capable of curing the diseased condition.
>
> Finally, these experiments lend support to the conception that naturally occurring pigmentary substances in foodstuffs play a rôle in nutritive processes.

This is plainly a factor not previously recognized. Its properties seem so different as to make it unlikely that there is any close relationship between this substance and the water soluble, heat-stable anti-pellagric vitamin of Goldberger. Does this mean that a deficiency of either of these two different and apparently unrelated substances may be the determining factor in pellagra?

It would, in our judgment, be unprofitable to press this question of theoretical interpretation at present, because there are still discrepancies to be cleared up as to the empirical facts regarding prevention of pellagra by different articles of food. Butter and carrots are much more favorably reported from New Haven than from Washington—in fact, regarding carrots, Underhill and Mendel say: "The discrepancies between the results of Goldberger and his associates and our own are so great as to prohibit attempts at explanation." And, on the other hand, the U. S. Public Health Service appears to attribute greater pellagra preventing value to wheat germ than is consistent with the findings of other laboratories.

But dietary means for the practical prevention of pellagra are now well known. In the mill village region of western South Carolina, where pellagra was extremely prevalent a dozen years ago and is now so greatly reduced as to be chiefly a memory, though still a threatening one, everybody, from the best educated to the most unlettered, refers confidently to "balanced diet" as the sovereign remedy and preventive.

Among the somewhat diverse impressions as to particular articles or types of food (for in most cases the diet has been enriched in several ways at once), there is such a general consensus of opinion that dairy products are especially effective, that in parts of the South the Red Cross is reported to be combating pellagra by the lending of cows—an excellent educational device, but not to be taken as meaning that physical proximity of cow and patient is essential, for milk contains the needed factor or factors in sufficiently stable form so that the cow can function at any distance that may be economically convenient.

Unanimity of opinion that milk is of high pellagra preventive value is equally consistent with any of the nutritional theories, because milk contains all the nutritionally essential factors, and is an outstandingly valuable source of nearly all of them.

But, as already suggested, this practical dietary means of combating pellagra is well known. Hence the somewhat confusing and apparently complex situation which confronts us as to the theoretical explanation of pellagra prevention need not retard the actual control of the disease, while the research which is needed for the clearing up of the theoretical problem may well be expected to add to our knowledge of the chemistry of normal nutrition and ultimately contribute to a still fuller understanding of the scientific foundations of positive health.

Sanitary Etiquette

THE U. S. Public Health Service has coined this name, which should come into general use. It carries a significance which everyone will recognize. Coughing and sneezing without protecting the mouth, indiscriminate kissing, insistence upon shaking hands, blowing the nose on a dirty handkerchief used later for some other purpose, and many similar practices which are too common, represent "unhygienic manners." The same is true of moistening various articles such as money, books, tickets, etc., with saliva.

The essence of good manners is consideration for others, and this applies to social customs as to hygiene. The Service suggests the writing of a book, "The Hygiene of Etiquette," and hopes that it will teach prophylactic manners and practical hygiene as well as social courtesy.

MINNEAPOLIS MUNICIPAL AUDITORIUM

Health Education in Illinois Teachers' Colleges*

MARY L. HAHN

Supervisor School Health Education, Division of Child Hygiene, State Department of Public Health, Springfield, Ill.

THE problem of health education in a college for teachers is a triple one, concerned first, with the personal health of the students, second, with the selection of subject matter, and third, with methods in health teaching.

The American Public Health Association poster entitled "Milestones of Public Health" gives the date, 1918, as the beginning of school health education. James F. Rogers, M.D., Chief of the Division of Physical Education and School Hygiene, U. S. Bureau of Education, makes a similar statement.[1] Whether or not we concur in this statement, we do know that since the year 1918 the term "health education" has almost entirely replaced the older one of "physiology" or "physiology and hygiene."

This paper will deal with health education in the Illinois teachers' colleges since the World War and the possibilities for the program of the future. During the post-war period two of the schools each added a physician to their staffs and one a nurse, and all the teachers of physiology placed more emphasis on health habits and methods of health habit training in the elementary school than before.

It was not until 1925, however, that a united effort was made to consider the health programs in the Illinois teachers' colleges and to suggest future policies. A survey of public health service in fifteen Illinois cities[2] was made by the Illinois Department of Public Health, with the guidance of Thomas G. Perrin, M.D., of the U. S. Public Health Service. This survey showed that the public health service in these cities was far from the standard set by the A. P. H. A. *Appraisal Form for City Health Work.* Of a possible 100 per cent of service, only 1 city was receiving as much as 80 per cent, and 6 cities were receiving less than 50 per cent. The survey showed inadequate expenditures for fundamental health services as well as inadequate

* Read before the Public Health Education Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

service—both the result of lack of information and appreciation on the part of the community. Education loomed large as the best possible means of stimulating public opinion in relation to these health services.

In order to find efficient educational channels, the advisory committee of the Illinois Department of Public Health in coöperation with representatives from the state teachers' colleges made a study of the health programs in these institutions in an effort to recommend measures for their stimulation and improvement. As a result of the work of this joint committee, a plan was drafted for training student teachers in personal and public health. Later this plan was submitted to and endorsed by the Illinois State Department of Public Health, the Illinois Normal School Board, and the presidents and faculties of the teachers' colleges. The special features of this original plan were: (1) health examinations and professional health service for all students, (2) proper living conditions for all students, (3) a required course in personal and public health, to be known as health education, and (4) additional required health courses for all 4-year students.

This brings us to the question—what are the results of this united effort to meet the present health education problems in the teachers' colleges?

HEALTH EXAMINATIONS

Prior to September, 1926, examinations had been given regularly only in 2 of the colleges where resident physicians were in charge. In the two years since that date all 5 colleges have required their entering students to be examined. Physicians from the State Department of Public Health have assisted several of the colleges in making these examinations, but for the most part the college physicians and local physicians have had this responsibility.

In 1 college which has no staff physician, the resident nurse, cooperating with the physical training department, conducts the examinations with the help of local physicians, dentists, and nurses. In the other 2 colleges the physical training department supervises the examinations. One college has added a nurse to its health service staff, but thus far this is the only one having both a resident physician and a nurse. As yet, 2 of the smaller colleges have neither.

One of the problems in connection with health examinations is that of records and record forms. The desirability of uniform blanks for this purpose has been discussed by the various persons in charge of the examinations, but a form satisfactory for general use in all 5 colleges has not been prepared. Further study is needed on this subject.

The matter of advising students in regard to correctable defects and considering health records in connection with professional ratings is difficult to handle in those colleges which have no resident physician. Much of the value of the examination is lost if time does not permit the physician to consider the findings with the student. Serious deficiencies of eye, ear or throat are usually referred for correction to the family physician, but the minor defects, which are a slow but certain drain on future vitality, are ignored for want of time unless the resident physician or nurse can arrange for a later conference.

The possibility of a student health council for stimulating personal responsibility in this connection has been suggested. Dr. Bailey's plan for a health councillor[3] might also meet this need. A few nurses, some physical training, and some health teachers are well fitted, because of their broad training, to serve as councillors in this field. The failure to have a resident physician or nurse as councillor is fundamentally due to lack of finances. The need of their services for the student group is recognized. The next step consists in recognizing it as of sufficient importance to overcome the financial difficulty.

The health examination prior to graduation will be as general as the entrance health examination only when the college staffs include both the physician and nurse.

The professional health service suggested in the plan included such features as hospital care, visiting nurse service and control of contagion. This last has always received more or less attention in all of the teachers' colleges, but the hospital care and visiting nurse service are of necessity limited because the professional health staff is limited. The time will doubtless come when the prospective student and his guardians will inquire as carefully concerning the health service offered by a school as they now inquire regarding its courses, professors, degrees, and social life. At the present time, however, a study of the catalogs of our 5 Illinois teachers' colleges shows that they give practically no information of this sort.

PROPER LIVING CONDITIONS

Each college has an excellent dormitory, but these house only a comparatively few of the women students. In the past, faculty committees and the deans have given considerable time and thought to the off campus students. The new plan, however, has stimulated new interest in and control of student living conditions. All householders who wish to furnish board or room to students are registered at the college. The houses on the approved list must meet certain requirements regarding heating, lighting, and ventilation, toilet and bath

facilities, screening, size of rooms, and control of communicable diseases. An extensive and excellent study of student housing conditions was recently made in 1 college, and special attention has been given the subject in each of the others. The question of uniform blanks for recording housing conditions has been discussed at the annual meeting of the teachers' college faculties. It should receive further consideration.

HEALTH EDUCATION COURSES

The health education course which was recommended in the plan for the teachers' colleges was the result of the findings in the survey of fifteen Illinois cities,[2] which pointed to the need for more general information regarding public health services.

The 5 teachers' colleges have always offered courses in physiology and sanitation which emphasized to a greater or less degree the problems of personal and public health. The object of the plan in this, as in other respects, was to arouse new interest in this field of education. To this end the new title, "health education," was suggested and this has been generally adopted. This course in health education was recommended as a minimum requirement for all 2-year students, and the teachers' college catalogs show that such is now the case. As a required part of this course the inspection of sanitary conditions within the local college community was suggested, which may include the homes or dormitories, school buildings, eating places, markets, dairies, and local health departments. In connection with the inspection of sanitary school buildings the *School Health Appraisal Form*, sponsored by the Illinois Congress of Parents and Teachers and the Division of Child Hygiene, State Department of Health, will be available during the present school year.

It was further recommended that all students engaged in supervised teaching at the time they are enrolled in the health education course be given a survey assignment in the training school. The report of this survey should include the sanitary care of the classroom and its equipment; the sickness, absence, and contagion rates of the training school pupils; and the health habits taught to the pupils. This part of the plan has not been generally emphasized. The *School Health Appraisal Form* should help to promote this type of inspection since it helps to state standards and also to check results.

A second feature suggested for the health education course is the scoring of the student's own health habits. As yet this feature of the plan has not been extensively used. At least two instructors in this course have had students check their practices in regard to the different health problems, as these are considered in the regular class work.

Usually these personal scores have been unsigned and have not been considered in making the individual's academic record. There has been considerable discussion among health education specialists concerning the grading of personal health-habit scores. If good teaching can develop well balanced appreciation and interest in health practices, it would seem wise to emphasize the personal rather than the academic value of these records. The use of the individual health inventory as reported in other schools seems to indicate that it is most valuable when personally discussed with the faculty adviser or when its use is sponsored by a student organization. The work of arranging a general score card for personal health practices is still before our instructors of health education.

The recommended plan suggested further, that students in the health education classes make a study of the health or hygiene textbooks officially used in the elementary and high schools of Illinois. The aim to train students to discriminate as to the presentation, the pedagogic correctness, and the scientific accuracy of this class of books has been generally included in this course. The instructors in 3 of the colleges have directed their students in making collections of health education books and other materials and evaluating their usefulness. Recently the School Health Education Service of the State Department of Public Health arranged an exhibit of such materials which it loaned to 3 of the colleges during their summer school sessions. This feature of the course can profitably be extended in the future.

Reference books to be supplied by the libraries for students in the health education courses were recommended as to type but not by title. In all of the colleges these have been supplied and for the most part generously. The question of a textbook for the course could not, according to the Illinois law, be decided by the committee. However, certain requirements were stated but thus far no one book has been found which satisfactorily meets them all. Government and other bulletins which deal with personal and public health have been used to overcome this difficulty.

ADDITIONAL REQUIRED HEALTH COURSES

The plan recommended that an advanced health course be required of every student enrolled in a 4-year curriculum. For the most part such advanced courses have been neither offered nor required. A few exceptions occur in connection with the courses in home economics, physical training, and high school methods, which offer home nursing, corrective exercises, and adolescent or mental hy-

giene problems, respectively. Health programs of college rank tend to begin and end with elementary or single term health education courses. Thomas A. Storey, M.D., indicated this in his report, *The Status of Hygiene Programs in Institutions of Higher Education in the United States,*[4] and Emma Dolfinger warned us against this danger in her address given at Atlantic City in 1926.[5] If we are to have adequate health programs in our public schools in the future, we must have superintendents, principals and teachers who are adequately trained in this field.

In Dr. Storey's report he made a very definite plea for developing a civic attitude toward health education, and he deplored the fact that the educational aspect of administrative hygiene programs is almost completely ignored. In the teachers' colleges some first-hand experience with the administrative problems of heating, lighting, water supply, sanitary care of school buildings and control of communicable diseases would certainly be invaluable to prospective superintendents and principals. The fact that reports from 2 of the Illinois teachers' colleges were included in Dr. Storey's study indicates that along with other schools throughout the country we have failed to utilize some of our own best opportunities.

According to the standards set by Dr. Storey's study, we also fail in extensively coördinating the various parts of the health program. This, he claims, must result in more or less duplication of effort and in less effective programs than could be expected from extensive cooperation. The Illinois teachers' colleges are no exception to this claim. An opportunity for considering the value of increasing all health education activities in the teachers' colleges is offered in connection with the annual meeting of the 5 faculties. During the past year a session of their program was devoted to "Health Education Problems in the Teachers' Colleges." The staff members from the departments of health service, biology and hygiene, physical education, and home economics were all present. The interest in the general discussions assured the success of plans for future meetings. It also helped to assure the success of health programs for Illinois teachers' colleges.

SUMMARY

The teachers' colleges in Illinois have been stimulated in their health programs not only by the physical records of World War recruits, but even more effectively by the findings of the survey made in fifteen Illinois cities. The plan for a health program which was recommended to and adopted by the teachers' colleges in 1925 has increased their activities so that (1) health examinations are, at pres-

ent, the rule rather than the exception; (2) efforts to require good living conditions for *all* students and to inspect them regularly have been increased or stimulated; and (3) the health education course required of all students emphasizes the value and the standards for public health service, the requirements for an effective public school health program, and the importance of personal health practices.

An increasingly effective health program in the future probably depends on (1) adding a physician and a nurse to the resident staff of each college where these are not now included; (2) increasing the number of advanced courses in health education and the opportunities for studying the administrative health problems of the training school, especially for prospective superintendents, principals, and special teachers of health instruction; and (3) on continuing the coöperative efforts of the various departments concerned with the health program in the Illinois teachers' colleges.

Communicability of Pneumonia

IT IS nearly 100 years since Dr. Samuel Henry Dickson, of Charleston, S. C., insisted upon the communicability of pneumonia, some 15 years before Pasteur began his experiments which founded the science of bacteriology.

All physicians of experience have observed instances in which the contagiousness of pneumonia could hardly be questioned. The New York City Department of Health during a 6-months period has studied 8,767 cases of pneumonia of which only 18 were secondary.

In view of the unquestioned fact that many pneumonias are due to specific germs, this small number of cases is rather surprising.

Probably other factors are also concerned, such as increased susceptibility. However, the fact that pneumonia is possibly communicable must not be lost sight of.—*Weekly Bull.*, New York City Dept. of Health, Mar. 9, 1929.

The Correction of Infant Mortality Rates for Residence

DOROTHY G. WIEHL

Division of Research, Milbank Memorial Fund, New York, N. Y.

THE death rate among children under 1 year of age is generally considered peculiarly sensitive to sanitary and other environmental factors. For this reason, infant mortality rates are under constant scrutiny wherever health work is being carried on, and their accuracy is of more than ordinary importance. To persons who are in close touch with the infant mortality statistics for any specific community it is a recognized fact that the officially recorded death rates do not always give a fair representation of local conditions, since the practice of using the number of births in the area as that of the infant population, and of relating to this population all deaths under 1 year of age within the area, without regard for the actual residence of the mother or infant, may result in a death rate which is not typical of the *resident* infant population. There are other inaccuracies in the records of infant mortality; but this paper is to discuss only those due to this reason.

Several conditions, of increasing importance, are involved. The modern trend toward hospitalization of maternity cases is bringing into cities with hospital facilities more and more mothers who are residents of rural communities and villages, with the result that the births recorded do not represent the infant population of the cities, nor of the surrounding districts. Deaths among these non-resident infants are not charged to the locality where the birth was recorded unless the death takes place before removal from the hospital. It might be expected that this would tend to lower the infant death rate in the communities with large numbers of non-resident births and to raise it in those from which these births were drawn. However, this result may be more than offset by other factors: (1) a high death rate in early infancy among the non-resident infants because of a comparatively large proportion of confinements having complications among those seeking hospital care; (2) deaths in the hospitals of non-resident infants brought for treatment after birth, thereby removing them from the locality to which the death should be ascribed and adding them to another. Obviously, to obtain an infant death rate which is repre-

sentative of a specific community, the two factors, births and deaths under 1 year of age, must be so refined that they apply to this community and also have a true relationship one to the other.

For an urban locality with good hospital facilities, the exclusion of births to non-resident mothers and of deaths of all non-resident infants will usually give a satisfactory resident rate, since the numbers of resident births or deaths which occur away from such a city are too few to materially affect any total rate. But for a rural community whose residents must seek hospital care in the nearest or most accessible cities, it becomes necessary to determine the number of births to resident mothers and also the deaths of resident infants which were registered in other places. The former method of refinement, the exclusion of non-residents, is relatively easy, but the search for births and deaths belonging to a specific community among those registered in many other communities is both time consuming and expensive. So far as is known to the writer, no study of infant mortality in a rural area has been published in which the death rate has been refined both by the exclusion of non-resident births and infant deaths and by the allocation to the area of resident births and deaths recorded elsewhere.

For Cattaraugus County, N. Y., such a refinement of the infant death rate for residence was undertaken and the results are here presented. The county has been coöperating in a rural health demonstration since 1923. It is in the southwestern corner of New York and had a population of about 73,816 in 1925, of which approximately 60 per cent was rural. The largest city is Olean (population 21,345), near Pennsylvania to the south and Allegany County to the east. The hospitals in Olean serve many residents of Pennsylvania and of Allegany County as well as those of Cattaraugus County. Salamanca (population 9,978), with one small hospital, provides care for a certain number of nearby rural residents. Residents of the northern and western parts of the county find Buffalo and Jamestown much more accessible than Olean, and some in the southern districts go to Bradford, Pa. Clearly, the problem of determining the death rate among resident infants in Cattaraugus is a dual one—not only must non-residents be excluded but the resident births and infant deaths in other areas must be considered. In this respect Cattaraugus County is in no way unique, as arbitrary political boundaries are meaningless so far as delimiting an integrated community.

In this study the recorded infant mortality rates are compared with two corrected rates: (1) that obtained by the method of excluding non-residents in the years 1921 to 1927, and (2) that obtained by allocation to the county of births and deaths under 1 year of age

TABLE I

NUMBER OF BIRTHS RECORDED IN CATTARAUGUS COUNTY AND IN THE URBAN AND RURAL SECTIONS COMPARED WITH THE NUMBER TO RESIDENT MOTHERS

Year	Total County			Urban			Rural		
	Total Number Recorded	Births in County to Resident Mothers	Total Resident Births*	Total Number Recorded	Births in County to Resident Mothers†	Total Resident Births*	Total Number Recorded	Births in County to Resident Mothers†	Total Resident Births*
1921	1,652	1,588	—	831	733	—	821	855	—
1922	1,578	1,535	—	773	675	—	805	860	—
1923	1,442	1,396	—	728	636	—	714	760	—
1924	1,474	1,412	—	762	645	—	712	767	—
1925	1,425	1,355	1,412	781	637	649	644	718	763
1926	1,417	1,318	1,374	816	633	643	601	685	731
1927	1,424	1,314	1,357	817	625	630	607	689	727

* Includes births to resident mothers recorded in adjoining areas.

† Number of recorded births to mothers not residents of the county were deducted and all births in the county allocated according to the place of usual residence of the mother.

which were registered outside, in addition to excluding non-residents, in the years 1925, 1926 and 1927. By the first method are excluded not only the non-resident births and deaths under 1 year but also the deaths of resident infants whose births were registered outside the county. The result is a death rate among resident infants born in the county. By the second method only non-residents are excluded and those resident infants born outside are added to the population together with deaths among this group which occurred elsewhere than in Cattaraugus County, the result being a death rate for the total infant population of Cattaraugus County. The first rate has the advantage of being easily derived from the data on the birth and death certificates registered in the county, while the second is more accurate, being free from the possible effect of excluding a selected group of infants.

The importance of making these refinements according to residence is considered in relation to the effect upon (1) the total infant death rate for the county, (2) the death rate from specific causes for the county, (3) the total death rate for the urban and rural parts of the county, and (4) the death rate from specific causes for the urban and rural parts of the county.

Only the areas adjoining Cattaraugus County have been considered as likely to have been the birthplace of any considerable number of Cattaraugus infants. These include Chautauqua, Erie, Wyoming and Allegany Counties, N. Y., and Bradford, Pa., to the south as shown in Figure I. All birth certificates from each of these

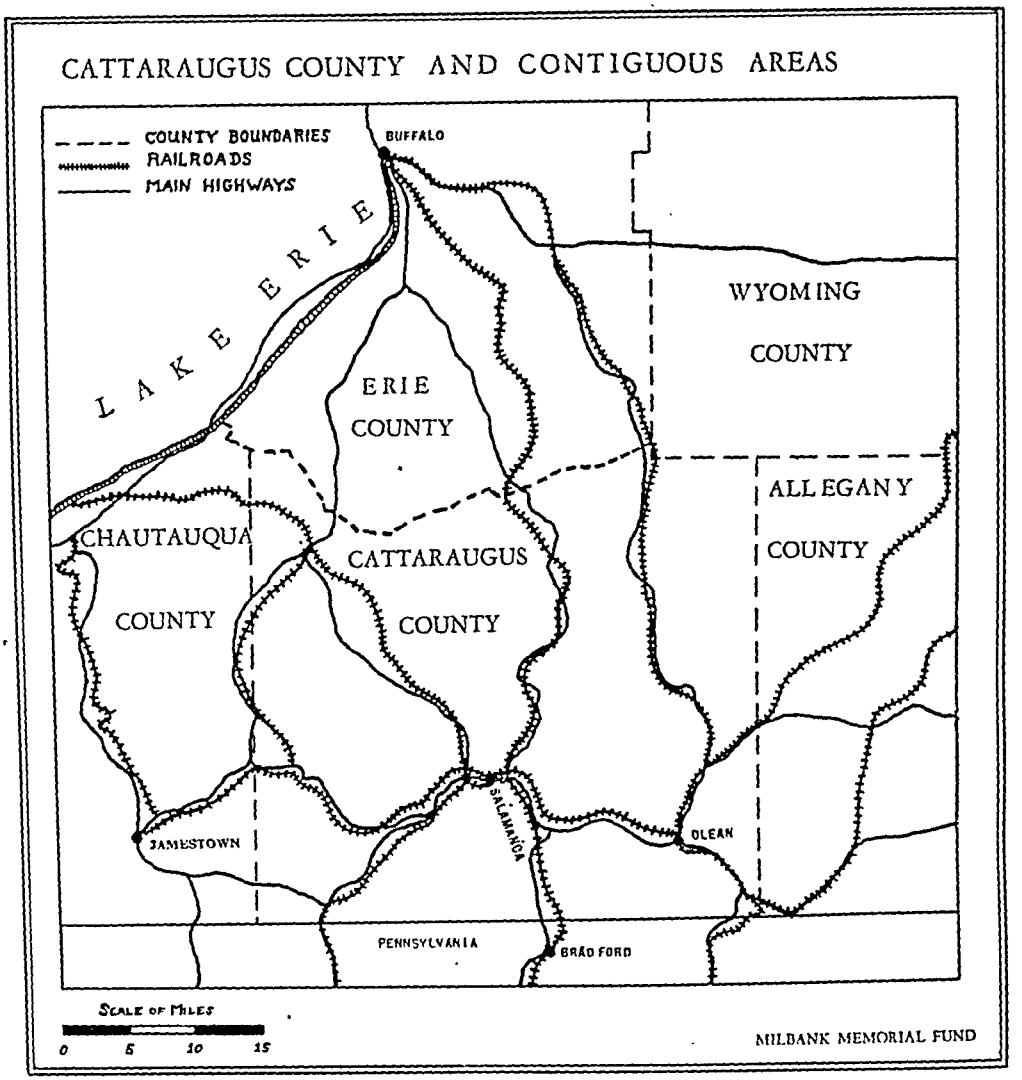

FIGURE I—Map showing accessibility by railways and highways of Cattaraugus County to neighboring cities and of neighboring rural districts to Cattaraugus County cities.

counties in 1925, 1926 and 1927,* filed with the State Registrar of Vital Statistics, were examined to find any births to mothers who were residents of Cattaraugus County, and the number of births to Cattaraugus County mothers recorded in Bradford, Pa., were obtained from the registrar of that city. The number of births recorded in Cattaraugus County, the number after excluding births to non-resident

* This part of the study was limited to 3 years because of the time involved. Approximately 19,000 birth certificates were scanned for residence of mother for each year.

TABLE II

RECORDED AND RESIDENT DEATHS UNDER ONE YEAR OF AGE FOR CATTARAUGUS COUNTY, 1921–1927

Year	Total Recorded in Co.	Non-resident Deaths Recorded in County		Recorded Deaths of Residents Born outside Co.*	Deaths among Residents Born in County	Deaths outside Co. among Res. Born outside	Net Resident Deaths
		Born in County	Born outside County				
1921	129	7	0	3	119	?	—
1922	145	2	2	4	137	?	—
1923	130	1	4	2	123	?	—
1924	97	4	2	3	88	?	—
1925	102	2	3	0	97	2	99
1926	95	7	1	2	85	1	88
1927	86	8	3	3	72	1	76

* Decedent has been counted as a resident unless information available definitely established the residence as outside the county at the time of death.

mothers, and the total number of resident births after adding those found in the adjoining areas are shown in Table I.*

The number of deaths under 1 year of age registered in the county is shown in Table II. The non-resident deaths and those of resident infants born outside the county, and not counted in the population under 1 year of age, are also given. Difficulty was experienced in classifying a few infants born outside the county from the data on the death certificate, but they have been counted as residents unless the information established the residence as outside the county at the time of death.† To obtain the mortality among the births to resident mothers which occurred outside the county, the names of the infants registered in adjoining counties of New York were checked against the index of all deaths reported to the State Department of Health. No check on the mortality among the births which occurred in Bradford, Pa. (8 or 9 annually), was made. Only 2 deaths in 1925, 1 in 1926 and 1 in 1927 were found to have occurred among these infants before they returned to Cattaraugus County.‡

On the basis of the data in Tables I and II, it is possible to compute the two corrected rates for the county; i.e., the death rate among

* See Downes, Jean. The Accuracy of the Recorded Birth Rates in Urban and Rural Areas, *J. Am. Stat. Assn.*, Mar., 1929, for further details as to the allocation of births and the effect on the birth rate.

† This practice was followed because these deaths occurred apparently from conditions contracted in the county and to balance any deaths outside the county of resident infants who changed their residence during the first year of life.

‡ As the total births to resident mothers in 1925, 1926 and 1927 registered in adjoining New York counties numbered 140, the 4 deaths among this group would give approximately the death rate in the first week of life among residents born in the county, which varied from 3 to 4 per 100 in the years 1921 to 1927.

TABLE III

INFANT MORTALITY RATE AS RECORDED IN CATTARAUGUS COUNTY COMPARED WITH THE MORTALITY RATE AMONG RESIDENT INFANTS, 1921–1927

Year	Deaths under One Year per 1,000 Live Births			Percentage Difference from Recorded Rate	
	Recorded	Residents Born in County	Total Known Residents	Residents Born in County	Total Residents
1921	78.1	74.9	—	−4.1	—
1922	91.9	89.3	—	−2.8	—
1923	90.2	88.1	—	−2.3	—
1924	65.8	62.5	—	−5.3	—
1925	71.5	71.6	70.1	+0.1	−2.0
1926	67.0	64.5	64.0	−3.7	−4.5
1927	60.4	54.8	56.0	−9.3	−7.3

resident infants born in the county and for all known resident births. These are compared in Table III with the annual rates based on the registered births and deaths.

From 1921 to 1927, the resident death rate for infants born in the county was lower than the gross registered rate in every year except 1925. The difference is not great, 5 per cent or less in every year but 1927 when it was 9 per cent, but the influence of the non-resident mortality has been consistently unfavorable to the Cattaraugus County rate. In 1927, exclusion of non-residents lowers the rate enough to increase materially the indicated decline over the 1926 infant mortality, and is important because it suggests an increasing effect of the non-residents on the county rate.

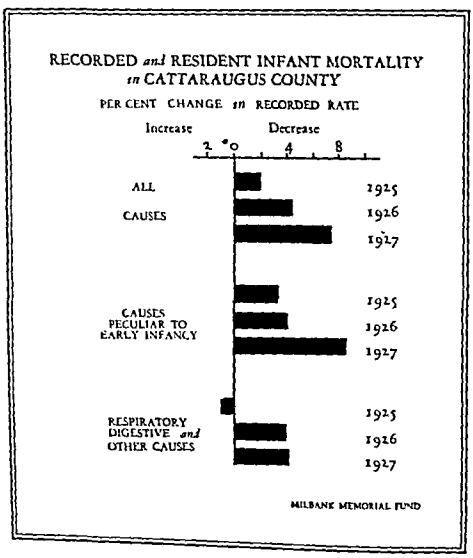

FIGURE II—The percentage change in the infant mortality rates officially recorded in Cattaraugus County resulting from correction for residence in 1925, 1926 and 1927.

The total resident death rate for children under 1 year of age also was lower than the crude registered rate for each of the years 1925, 1926 and 1927. The percentage difference between these and the recorded rate is shown in Figure II. The total resident rate differed scarcely at all from the death rate obtained for the residents born in the county in 1926; was a little lower in 1925; and a little higher in

1927. The infants born away from the county were less than 5 per cent of the total births to residents, and since the mortality among them was not high, the inclusion of these and the deaths among them does not affect the resident death rate so much as the exclusion of the non-resident births and deaths affects the registered rate.

A high mortality among the non-resident births in the county during the first few days of life is suggested by the fact that a reduction in the death rate results when the non-resident births and deaths are excluded. The mortality during the first week of life * among the non-resident births is compared in Table IV with the mortality among

TABLE IV

DEATH RATE IN THE FIRST WEEK OF LIFE AMONG NON-RESIDENT INFANTS BORN AT OLEAN COMPARED WITH THE RATE FOR RESIDENTS OF CATTARAUGUS COUNTY BORN IN THE COUNTY, 1921–1927

Year	Residents Born in County			Non-residents Born at Olean		
	Number of Live Births	Deaths under One Week	Rate per 1,000	Number of Live Births	Deaths under One Week	Rate per 1,000
1921	1,588	57	35.9	43	7*	162.8
1922	1,535	59	38.4	31	2	64.7

* Including two infants dying on the 8th day.

the resident births. Since all the non-resident deaths occurred at Olean, the rates have been computed on non-resident births in Olean. Although the mortality among the non-resident births fluctuated widely from year to year, it is clear that the death rate in the first week of life was higher than that among resident births, the average for the 7 years being nearly twice as high. This higher death rate in early infancy among the non-resident births is explained by the fact that they are a selected group which includes a large proportion of maternity cases for which some complication of confinement was expected.

The deaths which occurred among the non-resident births before removal from the county resulted for the most part from premature

* Few deaths occurred among the non-resident births after the first week; in 1921, 2 infants died at the age of 8 days; in 1924, 1 died at the age of 16 days; and in 1926, 1 died at 16 days and one at 11 months, the latter infant obviously having been brought to the hospital a second time for treatment.

birth, injury at birth or some congenital cause. It is to be expected that their exclusion will have a greater effect on the death rates from these specific causes than on the total infant mortality rate. The infant death rate from the general group of " early infancy " causes as registered in the county is compared in Table V with the rate for the resident infants born in the county and for the total known resident infant population. From 1925 to 1927, the " early infancy " mortality among all resident infants was lower than the registered rate, and the difference increased from 3.3 per cent in 1925, to 8.5 per cent in 1927, as is shown in Figure II.

The " early infancy " mortality rate for resident infants born in the county was also lower than the recorded rate. It differed only slightly from the total resident rate, and, being available back to 1921, it further indicates that non-resident deaths have had an increasing effect on the recorded mortality from " early infancy " causes.

The corrected infant death rates from all causes other than those " peculiar to early infancy " also are compared with the registered rates in Table V. These deaths are due chiefly to communicable, respiratory and gastrointestinal diseases. As deaths from these causes rarely occur in the first few weeks of life, and no death was reported

1925	62	5	7	50	0	50
1926	61	8	3	50	1	49
1927	50	11	3	36	1	35

* No deaths of urban residents were registered in rural districts. One death occurred in New York State outside the county in 1925, none in 1926 or 1927.

fancy " is lower than the registered rate in 5 of the 7 years, the difference varying from 0.7 to 1.9 deaths per 1,000, with a maximum decrease of 5 per cent. The total resident rate is slightly higher than the rate for residents born in the county in 6 of the 7 years; so the difference between the recorded and the resident rates obtained by the exclusion of non-residents is somewhat greater than the difference between the recorded and the total resident rates.

Although in these years the difference between the two resident rates is not marked, the rate for the total resident infants is the more truly representative. In obtaining the death rate among infants born in the county, the deaths of certain *resident* infants whose births occurred outside the county must be excluded although conditions leading to these are chargeable to the county. This exclusion has proportionately smaller effect on the rate for broad groups of causes than on the rate for a single cause. Thus, there may have been 5 deaths from diarrhea, one of which was a resident infant born in Buffalo; the exclusion of this death will reduce the mortality rate for this cause nearly 20 per cent since the population base differs only slightly for

TABLE VII

NUMBER OF DEATHS UNDER ONE YEAR OF AGE REGISTERED IN RURAL CATTARAUGUS COUNTY AND NUMBER THAT WERE RESIDENTS OF RURAL AREA, 1921–1927

corded in the county to the place of usual residence of the mother, in addition to adding those resident births and deaths recorded in outside districts. The number of deaths of children under 1 year of age registered in urban and rural Cattaraugus 1921 to 1927 is shown in Tables VI and VII, together with the number to be deducted or added, to obtain the net number of deaths among the resident population under 1 year of age.* Two resident totals are shown for each area; one being the number after allocating the deaths of resident infants born in the county and deducting those born outside the county, as well as the non-resident deaths; the other being the total number of known resident deaths after allocating all deaths registered in the county and those known to have occurred outside. The rates obtained when these totals are related to their respective populations are shown in Table VIII.

* The population under 1 year of age, i.e., births to residents of urban and rural Cattaraugus County after allocating to usual residence, is given in Table I.

The infant death rate, both urban and rural, is lowered in most of the 7 years when based on either the net number of deaths among the resident population under 1 year of age born in the county, or the total, including those born outside the county, instead of on the number of deaths and births recorded in the urban or rural districts. The difference between the two resident rates is very slight in nearly every year. The per cent that the corrected rates are above or below the registered rates is indicated in Table VIII. The lower resident rate in the urban section is explained by the relatively high death rate in the first week of life among the births to non-residents of the urban districts, and to the deaths among non-resident infants brought to Olean for hospital care; but the lower resident rate in the rural section results from a marked increase in the population under 1 year of age when all births to rural mothers have been allocated to that section. Since both rates are reduced, the relative infant mortality

† Deaths outside the county from causes other than "early infancy" would be rare and are offset by deaths in the county of infants who became residents sometime after birth.

from all causes in the two areas is not materially changed except in 1921 and 1926.

From year to year, the effect on the infant mortality rate of allocating all births and deaths in the first year of life to their place of usual residence varies widely for both urban and rural rates. No estimate of the probable effect of this factor in one year could be based on the known experience in another year. There is, however, a fairly definite indication that the trend is toward a widening difference between the uncorrected and the corrected rate for both.

In Table IX, the infant death rates in Olean and Salamanca, and in Table X the rates for the rural district have been classified as those "peculiar to early infancy" and all other causes, chiefly respiratory, gastrointestinal and communicable diseases. The rates based on the registered births and deaths in each year from 1921 to 1927 are compared with the two series of rates for resident infants.

The effect of correction for non-residents on the urban mortality from "early infancy" conditions varies widely for these 7 years, ranging from a decrease of 27 per cent in 1921 to an increase of 5.6 per cent in 1926 when residents born in the county are considered. Again the total differs only slightly from the incomplete resident rate. For the rural part of the county, the death rate from "early infancy" causes in the earlier years was increased by the reallocation of the births and deaths of rural residents recorded in urban localities, but in most recent years the rate is reduced. A maximum increase by correction for residence of 11.5 per cent is indicated in 1921 and a maximum decrease of 8.7 per cent in 1927. Since the annual rates as well as the effect of correction show wide annual fluctuations, the following comparison of the corrected and uncorrected rates for the most recent 3 years with the previous 3-year period in each area is of interest:

DEATHS FROM "EARLY INFANCY" CAUSES PER 1,000 LIVE BIRTHS IN CATTARAUGUS COUNTY

Period	Recorded Rate	Rate among Residents		Per cent Change	
		Born in Co.	Total	Res. Born in Co.	Total
Urban					
1922–1924	51.26	49.08	—	−4.2	—
1925–1927	50.95	49.08	48.91	−3.7	−4.0
Rural					
1922–1924	47.07	48.60	—	+3.3	—
1925–1927	42.66	41.59	41.42	−2.5	−2.9

The corrected resident rates for the urban and rural parts of the county bring out more definitely than the officially recorded rate two

interesting indications: (1) the mortality from "early infancy" in the two areas was almost identical in the earlier 3-year period; (2) the rural rate declined 15 per cent in the later 3-year period compared with 10 per cent shown by the recorded rates.

The total resident urban death rates from respiratory, gastro-intestinal and communicable diseases are from 1 to 13 per cent higher than the registered rates, and the difference is more marked in the total resident rate than in that for residents born in the county. The opposite is true of the rural death rates, from these causes: For the rural section the rates are lower after correction for residence, and

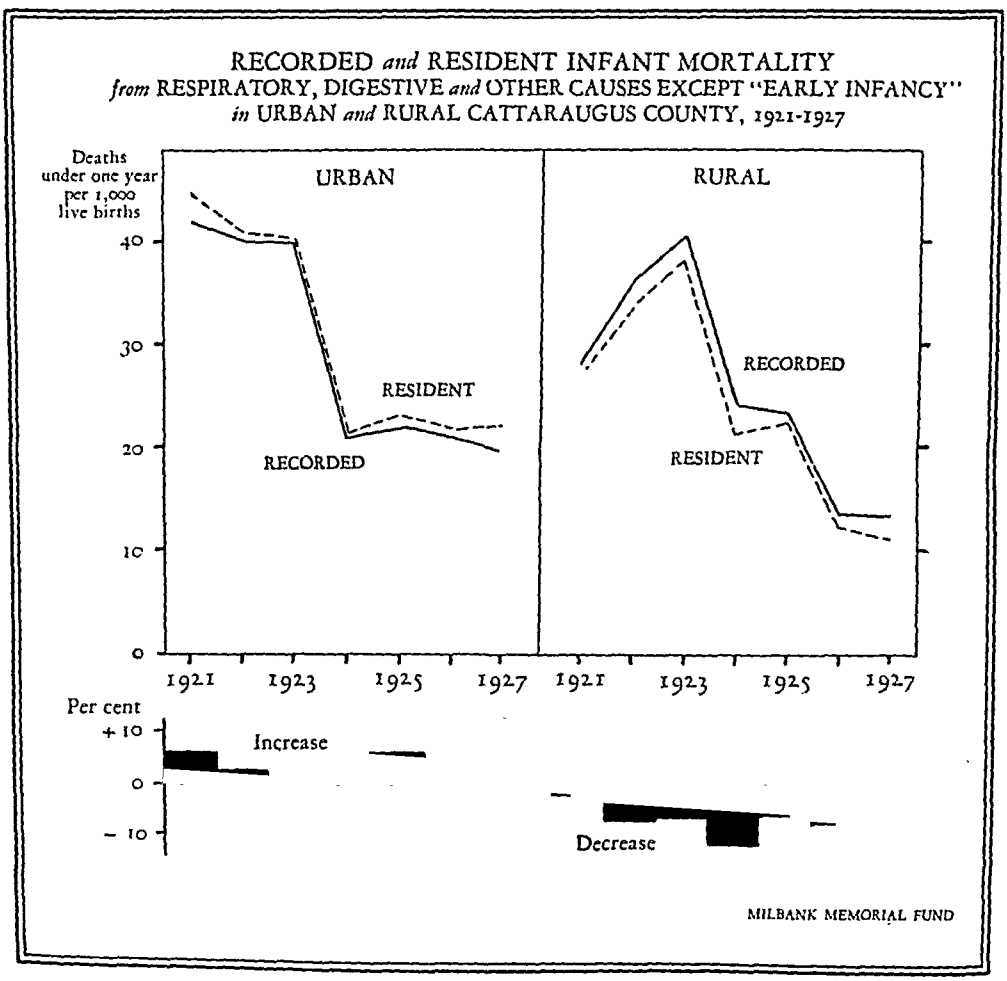

FIGURE III—Infant mortality rates from all causes except "early infancy" in urban and rural Cattaraugus County as officially recorded compared with the resident rates and the percentage change resulting from correction for residence, 1921–1927.

the total resident rate shows less difference in most years than the rate for residents born in the county. Since the urban rate is increased by correction for residence, and the rural rate is lowered, the divergence in the rates for the two areas is widened, as shown in Figure III. The corrected rural mortality from communicable, respiratory and gastrointestinal diseases is lower than the urban in every year, whereas the registered rates were higher in 3 of the 7 years, and in the other the difference between the two is widened.

SUMMARY

It seems essential that the infant mortality rates should be corrected for residence if an accurate picture of the changes in the death rates from year to year or of the comparative mortality from specific causes in different areas is to be obtained. In Cattaraugus County, the officially recorded infant mortality from all causes for 1927 was 15 per cent lower than the 1925 rate, while the resident rate showed a decrease of 20 per cent; the recorded death rate from causes peculiar to early infancy was 11 per cent lower in 1927 than in 1925, but the corrected resident rate was 16 per cent lower in 1927 than in 1925. Thus, the inclusion of non-residents reduces the decline in the death rate indicated for recent years.

If the infant mortality rates in urban and rural sections are compared, the results are very unreliable unless corrected for residence.

The difference between the death rates for resident infants born within the county and the rates after reallocation to the county of resident births and deaths occurring outside the county is not striking in 1925, 1926 and 1927, for which both are available. Since the total resident rate is sometimes higher and sometimes lower than the rate obtained after excluding all non-residents and the group of infants born outside the county, differences between mortality from specific causes or in different areas may be either widened or lessened by using the former rate instead of the latter. The total resident rate, being more accurate, is to be preferred, but the use of the rate for residents born in the county yields fairly good results unless a single year's rate or a single cause of death is selected for close scrutiny. In using rates for residents born within the county, it would be necessary, however, to check these against a total resident rate from time to time because hospitalization is still increasing, and because the opening of a hospital in some nearby city, or provision of hospital facilities within a rural area may bring about a change.

Although Cattaraugus County is a small area, the difficulties encountered in attempting to study its infant mortality records in con-

siderable detail are typical of those to be found in the average county. The fact that there has been a health demonstration in this county since 1923 may have brought about a more rapid increase in hospitalization of maternity cases than has occurred in other rural counties but the trend toward hospitalization is general. Few, if any, counties will be so situated that the rural populations will be served entirely by hospitals within the county limits or that the hospitals will not be used by non-residents. Correction of rural rates for residence is more difficult than of the rates for an urban community well supplied locally with hospital facilities, because in the latter case the exclusion of non-residents will usually be sufficient and the information is available at the local registrar's office. For a rural area, for which it is necessary to trace the resident births which occur in outside hospitals and determine the deaths among them, a corrected resident rate is very difficult to obtain. This is a serious handicap in the analysis of rural infant mortality, and of other rural death rates. The publication of resident data by the central bureaus (state and federal) would be of great assistance to persons interested in following the mortality experience of a specific community.

ACKNOWLEDGMENTS—Acknowledgments are made to the Cattaraugus County Health Department, especially to Frances King, Statistician, for assistance in compiling the data, and to the Bureau of Vital Statistics, the New York State Department of Health, for access to the certificates.

New Booklet on the Care of the Baby

UNDER the title, "Your Baby's Care," Dr. Susan P. Souther of the Children's Bureau of the U. S. Department of Commerce has prepared an interesting 32-page booklet on the hygiene of the child under 2 years of age. This booklet has the approval of the Medical Advisory Committee of the American Child Health Association and a Committee of the State and Provincial Health Authorities of North America. It is attractively printed in readable type with interesting illustrations. To add to its usefulness as a textbook for the mother of the young child, the booklet includes an index and a table of contents. This newest publication on child health is offered free to health officials and social agencies by the Life Conservation Service of the John Hancock Mutual Life Insurance Company, Boston, Mass. Sample copies may be obtained at any time after April 25.

Beverages*

RELIABLE estimates indicate that 12 billion bottles of soft drinks will have been consumed in the United States in the year 1928, an increase of 1 billion bottles over 1927. In addition, stands and stores selling orange and other fruit drinks may be found in almost every city business block. Not only has the beverage industry greatly increased sales, but real progress is being made in using natural fruit beverages, chocolated milk products, etc., in place of artificially colored and flavored and sometimes artificially sweetened drinks.

A review of the literature shows an almost total lack of activity in the health aspects of beverages. While some research work has been done by the fellowship established at one of our state colleges by beverage manufacturers, it has been mostly along commercial lines. It would seem as though public health officials were not interested in beverages or foods, until an epidemic occurred. This apparent inactivity is not confined to research, but is evident in legislation for the control of the industry.

The secretary of a group closely allied to beverage production recently issued instructions for the labeling of artificial raspberry soda. To be legal in all states, eleven different forms of declarations of color and flavor were required. There is almost as great variation in bacterial and chemical standards.

Some states have recently enacted laws that should make for better control of the soft drink industry. Michigan's law requiring the registration of all beverages provides that the registration fee shall go toward the maintenance of a fund for the inspection and control of the beverage industry. Indiana's water law requires that beverages meet a certain standard bacterial count as well as the usual colon standard.

In Chicago, stands are operated in almost every block of the business district, selling orange drinks—some natural fruit, and others entirely artificial. In May, 1926, sanitary control was inaugurated, requiring the taking of weekly samples for bacteriological examination. Orange beverages were required to comply with the standard for drinking water on interstate carriers. During 1926, 542 samples were examined, of which 166, or 30 per cent, showed the presence of colon bacilli. In 1927, 1,375 samples were examined, and 10 per cent

* Report of the Committee presented to the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

were colon positive. In May, 1928, a survey revealed that some orange drinks contained as much as 20 per cent fruit juice, others as little as 2½ per cent, while still others were wholly artificial; yet with the aid of flavoring extracts and colors, all looked the same to the consumer.

In view of present knowledge as to the value of the vitamin and mineral elements in fruit juices, Chicago officials hold that control of the amount of fruit juice in an orange beverage is just as important, from a public health standpoint, as the control of butterfat in milk. Regulations promulgated June 23, 1928, require:

1. Fresh fruit orange drinks must contain 10 per cent orange juice. Artificial drinks must be sold as such and patrons advised of the contents.
2. Employes submit specimens of feces and urine for typhoid examination.
3. If orange peel is used in the manufacture of beverages, the oranges must be subjected to a chlorine bath sufficient to disinfect the exterior.

While orange drinks have been the common beverage in Chicago, fruit juices such as pineapple, lemon, and grape are popularly used in other cities, and an investigation will probably reveal conditions similar to those found in Chicago previous to the adoption of these regulations.

COMMITTEE RECOMMENDATIONS

It is recommended that the membership of the Committee on Beverages be increased to 6 and that this committee be divided into 3 sub-committees, each having a definite, prescribed program along the following lines:

1. A study of methods of manufacture of beverages, and machinery used, with the object of developing types of machinery that may be easily cleaned and safe to use.[1] Levine states that with some types of filters water has a higher bacterial count after filtration than before.
2. A study of methods of inspection and legislation, with the object of developing a uniform method of inspection and control; the sub-committee on this subject to have as its goal the production of a standard beverage law or ordinance similar to Frank's standard milk ordinance.
3. A study of foreign substances now used in beverages such as saccharin, saponin and preservatives, with the object of determining their usefulness in beverages and their harmful effects on man.

Steps in Planning a Health Education and Publicity Program*

Why Have a Plan?

MARY SWAIN ROUTZAHN

Russell Sage Foundation, New York, N. Y.

SUPPOSE that you had time to plan health education and publicity a year ahead. Suppose you were to go about it as though it were an engineering problem, not an odd job for spare moments. How would you analyze the steps in your year's program? Would you, perhaps, begin by setting down your objectives? It is not likely that you keep a card file of possible objectives from which two or three could be selected at random. How then, does one decide what are to be the goals for a given year, say, 1929? How are the best methods of reaching them determined?

These questions are not intended to bring forth broad and impressive statements of purpose, but real, practical, working plans. Each of the papers here presented discusses one essential factor in this kind of planning. No exact formulas are offered; we start with two propositions which we believe to be sound:

1. Advance preparation of a carefully thought out program is essential to good work in health education and publicity.

2. The basis for program making is a study of one's situation so as to determine not only what sort of a response should be sought from the public, but also what is the best procedure in trying to get that response.

Both the selection of goals and the steps to be taken in arriving at a program for reaching them are discussed in the group of articles which follow.

In order to obtain examples of publicity programs for discussion, a request was sent to health departments and health organizations to submit outlines of their plans for the year ahead or for a given project. It was suggested that the outline should answer these questions:

1. Why will you undertake what you are planning? What facts or circumstances or desires lead to the choice of activities?

2. What results are sought? What are the objectives of the responses hoped for?

* Papers from a symposium of the Public Health Education Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17 and 18, 1928. Papers by C.-E. A. Winslow, Dr.P.H., and Franklin Fearing, Ph.D., will be published in the June JOURNAL.

3. To whom will you address the messages? What groups or kinds of people will you try to reach as being most important in getting the results wanted?

4. What is to be the message—the chief talking points—in each special activity?

5. How will you approach the selected groups or kinds of people? What do you believe to be their attitude toward the subject, and their understanding or lack of understanding of the subject? What motives, such as fear, the desire for good looks, civic pride, etc., will be appealed to in seeking action?

6. What are to be the methods and materials used in handling the several situations? List what you will do and what forms of publicity you will use.

In addition to the above please list the routine activities, such as day-by-day news which does not relate definitely to the program of effort for the year, the bulletin or house organ, giving out printed matter or information on request, etc.

7. Supplementing the above it will be useful to make up a calendar showing what is to be done month by month in both the preparation and carrying out of the publicity activities.

About 30 programs were received in response to the request. A few of these gave definite and clear-cut answers to the whole list of questions. Some of them gave lists of methods to be employed together with brief mention of the topics to be emphasized. One publicity calendar told what schedule would be followed month by month as suggested in question 7.

The starting point in mapping out a program is naturally its objectives. For our present purposes, we may assume that objective means the response desired from the persons addressed. In most instances the expected response takes the form of readiness to act in certain ways immediately or when the occasion arises. An analysis of the circumstances likely to influence the action of those to whom publicity is addressed is an important factor in the choice of objectives.

For example, a program of education in personal hygiene directed toward persuading city dwellers with small incomes to follow a proper diet, sleep with the windows open, dress to suit the weather, stay out of crowds, exercise daily, take enough rest, and avoid worry, brings the planner face to face with a number of social situations closely bound up with the ability of the average citizen to act on such advice. One must consider the price of eggs, the architecture of homes and offices, fashions in clothing, the transportation problem in cities, modern family life with its restraints, responsibilities and frictions for the individual member, the tremendous urge to acquire debts through instalment buying, and the continuous uncertainty of employment.

In planning health education, shall we leave these questions alone or try to adjust our advice to the persons who are thus handicapped? Shall we even take a hand in changing the conditions? In the present discussion fortunately we do not need to decide which course to fol-

low. We need only to observe that an effort to plan health education so it will be acted upon, instead of merely giving it out in a " take it or leave it " manner, sometimes brings us face to face with problems which it is more comfortable to ignore.

In contrast to the complexities of an educational program directed toward daily habits of living, the diphtheria campaign illustrates a fairly simple situation, in which to decide what we wish people to do, who are the persons to reach, what method of approach will influence them to action, and so on. The audience is easily identified; the thing to be done can be described simply and clearly; and it is reasonable to look forward to completing the whole task in a few years. Here analysis yields results in sound and workable programs.

The next step is to select and identify the persons to whom publicity is directed. This question is closely bound up with objectives. For example, the objective may be to persuade *parents* to see that the child's birth is registered, or *citizens* to vote " yes " on a bond issue.

Another factor in the health education program is the selection of the subject matter. Some of us solve this problem of selecting the message by telling all we know; others of us tell what is uppermost in our minds.

Some understanding of the mental attitudes of persons to be approached in matters of health conduct is important to every phase of a health education program, from the picture on the cover page of a folder to the signature of a letter. Principles of attention, interest and motivation must form the basis of the plan of approach to a particular public.

The forms of expression and the channels through which information from health organizations goes to the public should be adapted to the audiences and the subject matter. In considering the publicity methods to be used in a given situation, we are too often prone to follow the path of least resistance, to select methods which are immediately feasible due to the special ability of some member of the staff or to some special opening made possible by a contact with an interested newspaper or a friendly service club.

Ten years ago the writer listed 60 forms of publicity available for working up attendance at an exhibition. That was before the days of radio, talking pictures, air mail delivery, animated cartoons and other recent inventions for rapid, wide and graphic expression of facts and ideas. With such a wide range of methods to choose from, the planner who states that he expects " to use every available avenue for reaching the public " places himself under the suspicion of having no plan at all, or, at least, no appreciation of the wide range of choice open

to him, and of the importance of selecting wisely the methods to use under any given circumstances. Discussion of this essential part of planning, namely the selection of appropriate forms of publicity, is omitted from this symposium, since it is rather fully treated in easily available books and articles.

The preparation of a calendar or schedule has also been omitted from the discussion. In planning the year's work such a schedule naturally divides itself into: (1) routine publicity, such as publication of a bulletin, release of current news to the newspapers, responding to requests for printed matter, and the like; (2) special projects relating to the season of the year or having some other element of timeliness; and (3) emergency or " opportunist " publicity which seizes upon an unexpected situation, like an epidemic, as an occasion for a special educational campaign.

Emergency events cannot, of course, be scheduled; but the program as a whole may be made flexible enough to allow for substitution of publicity on unexpected events or situations when the occasion arises.

In practice, health education is often considered not as a distinct project but as an incidental part of the work of conducting clinics, nursing service, or administrative work. It is carried out by health officers or executive secretaries who combine it with other duties. The procedure here outlined recognizes the close relationship between publicity and service or administrative work, but considers it as a separate unit of work with a technic and objectives of its own. This fact needs to be kept in mind throughout the series of papers which follow in order to avoid confusion.

Objectives of Publicity—On What Basis Are They Selected?

HOWARD WHIPPLE GREEN, FELLOW A. P. H. A.

Secretary, Cleveland Health Council, Cleveland, O.

SUCCESSFUL health programs have definite objectives. The reason for the program may be a high death rate, a high infant mortality rate, a high diphtheria case or death rate, a high tuberculosis death rate, increasing cancer or heart disease mortality, or extensive sickness. When the facts are once established a further statistical analysis must be made in order to obtain a definite idea of the particular cause of the difficulty. The reason for its existence must be sought.

Let us, for example, consider means for the further reduction of infant mortality. The infant mortality rate has decreased considerably during the past two decades. The death rate of infants in Cleveland in 1910 was 147 per 1,000 births; 2,033 deaths occurred. The rate in 1927 was 59; 1,133 deaths occurred. The much larger number of births occurring in 1927 than in 1910 is reflected in these rates.

The first question would probably be "What causes these deaths?" We find that 790, or 39 per cent, in 1910 were caused by diarrhea and enteritis, and 252, or 12 per cent, by premature birth. In 1927, 99, or 10 per cent, were caused by diarrhea and enteritis and 353, or 34 per cent, by premature birth. The deaths due to diarrhea and enteritis have decreased greatly, and fairly regularly each year. A considerably further decrease is not possible. Even though no deaths due to diarrhea and enteritis occurred, the infant mortality rate could only decrease from 56 to 51.

What is the significance of this fact? Simply this—if, as in Cleveland, the deaths due to diarrhea and enteritis under 1 year have approached an irreducible minimum, attention must be directed to other important causes of infant deaths. The next most important cause is premature birth. It is also evident that the percentage due to prematurity has increased, although the rate is about the same in 1927 as in 1910, namely, 18 per 1,000 infants born alive. However, the largest number of infants in 1927 died because they were prematurely born. An extension of the program already demonstrated to be so effective in reducing the deaths due to diarrhea and enteritis is not indicated because this program has had no effect in reducing the deaths due to premature birth.

No demonstrable effect—why? The greater number of deaths due to diarrhea and enteritis occurs in the last 7 months of the first year of life. The greatest number of deaths due to premature birth occurs during the first 7 days of life, 60 per cent in the first day, and 88 per cent in the first week. It is evident, therefore, that what is done to prevent deaths from this cause after the infant arrives is of little avail because the infant is with us for so short a time. Therefore attention must be directed to the period before birth, and to the institution of prenatal work.

We have found our audience and have defined our fundamental problem. Our basic objective is to reduce deaths due to premature birth. Our audience is the expectant mother. We must now search for the cause of deaths due to premature birth and arrange our publicity to interest our audience and eliminate the causes.

We can emphasize the nutrition necessary for the mother in order

to build sound teeth and good bones for the expected baby. We must interest the pregnant woman in giving birth to a baby free from syphilis. We may even attempt to interest her in mental hygiene. But as yet we have not the stimulus to get our audience and allow us to dispense our instruction, until we remember the layette. What preparation is necessary for the new baby? What clothes are needed? How shall these be made? Now that we have the stimulus, we can push forward the publicity with an assurance of results, because human interest has been aroused.

The tuberculosis death rate is decreasing slowly but surely. For white males between 15 and 25 years of age in Cleveland it decreased 52 per cent in 12 years, but for white females between 15 and 25 years of age only 14 per cent. There we have the fact basis established. The problem is before us—what is the solution?

We make our suppositions, we use our scientific imagination, and to what avail? We have a definite objective for our publicity program—our audience defined!

We decide that girls must be interested more in their health than in their boyish form and their social whirl. But health by itself is of no interest to the modern young lady. Interest her in health as it relates to vitality, good looks, attractiveness, personality, success, and it becomes of first importance.

Contacts with girls of the age we wish to reach may be made most readily through the school teacher, club leader, Sunday School teacher, employment manager, or leaders of girl scout, camp fire, and girl reserve groups. Convincing the leaders of these groups of the importance of health is the first and most important step. Furnishing them with material with which to interest the girls is no less important, but much easier. Finally, placing interesting material directly in the hands of the girls at frequent intervals clinches the program.

DISTRICT PROBLEMS

Statistical analysis indicates the relative importance of our various programs.

We may wish to defeat a chiropractic licensing bill. Our analysis shows many of our voters to be antagonistic to physicians. They consider physicians perhaps as members of a medical trust. Why then should they, as poor voters, strengthen this trust? The objective is definite. The emphasis must be shifted to that of showing the physician as protecting the public health rather than allowing argument to arise between physician and charlatan. The campaign must have as its objective the defense of the public health and interest not only

doctors but dentists, druggists, employment managers, and allied groups.

Antagonism breeds antagonism, but a promotion program for the public good can unite under its banners every individual and organization with this as an objective.

Publicity connected with social work, especially in other fields than public health, has been chiefly concerned with the raising of money rather than the correction of existing faulty basic conditions. The chief reason for publicity methods having been confined to this one field has been a lack of definite statistical data relative to the community, and particularly to various sections of the community. Studies of the composition of the population of large cities and of the particular ills from which it is suffering have been made at various times and in various places. However, the minute analyses of various sections are imperative as a basis for any attempt to alter faulty conditions. Such analyses are being undertaken in Cleveland, using the fundamental data collected by the United States Government each 10 years relative to the populations of small areas of constant geographical boundaries, known as census tracts, or sanitary districts. Social data of all kinds are being collected relative to each census tract. These include the births, causes of death, causes of sickness, the chronically ill, crippled children, dispensary cases, cases cared for by family case work organizations, mothers' pensions, juvenile courts, visits made by the visiting nurse, illegitimate births, houses of prostitution, and so on.

In regard to census tracts, the following points are significant: One may have only 10 persons per acre, another 141 per acre; one may have a population with 40 per cent of the adults illiterate, i.e., unable to write any language; in another 50 per cent of the population may be under 15 years of age, in still another, only 4 per cent. The people living in certain census tracts seem to come to more grief than those in others. A tract in which the family welfare case rate, the tuberculosis death rate, the infant mortality rate, and the rate of juvenile court cases are high, in which houses of prostitution are numerous, in which rents are low and housing conditions bad, merits the attention of any publicity person.

The causes of the conditions must first be sought, the objectives of the publicity determined, the audience called to attention. Then and only then may reform be basic and improvements permanent.

The objectives of the publicity must be based on facts determined with scientific accuracy, and when determined, the audience to be reached is defined, and the methods to be employed may be fixed with some degree of exactness.

Audiences--How to Select and Classify Them

MARJORIE DELAVAN, FELLOW A. P. H. A.
Michigan Department of Health, Lansing, Mich.

JUST as the objectives of a health education and publicity program are determined by a thoughtful and unprejudiced analysis of existing conditions, so are the audiences to be approached defined by the objectives. The term "audiences" in this sense is not limited to those who listen to lectures, but includes everyone who can be reached by any of the publicity avenues at our command.

Audiences are always, in one way or another, selected. They are naturally and automatically selected by the objective chosen. They may then be further and more arbitrarily limited on the basis of available finances, personnel, or time. Our newspaper stories, posters and exhibits carry on their own selective process by the material that they present. Since selection is inevitable, we can agree that it may well be made a conscious and reasoned proceeding in view of its importance to the success of the campaign.

The first step in choosing our audiences is to decide what individuals and groups are directly and indirectly concerned in the attainment of our objective. We have become so thoroughly organized that we think in terms of groups. The organized group is tangible, it has a president who can be convinced, a well defined and counted membership, and a regular meeting day. In some types of campaigns, such as teaching personal hygiene to school children, dependence on the organized group is a safe solution. When time and funds are limited it is often the only one, but with adult groups, where belonging is a matter of choice, it is usually incomplete because the very person we wish most to reach may not be enrolled. Valuable and temptingly convenient as it is, it can never take the place of the individual approach whenever the latter is feasible.

Covering the organized groups of a community, a feat which we are prone to view with satisfaction, is not equivalent to reaching the whole audience. In any publicity campaign it is well to burn a little midnight oil in considering the person who does not belong to clubs.

Going back to the mechanics of the selective process, the audience of primary importance is made up of the individuals upon whose direct action rests the attainment of the objective. In Mr. Green's illustration this person was the prospective mother. In a diphtheria protection program it is the father and mother of the diphtheria-age child. In periodic health examination campaigns it is the adult who comes

within the age group threatened by the degenerative diseases. In a vaccination campaign it is the unvaccinated—or un-revaccinated—person. In a bond issue for a safe municipal water supply the voter who drinks the water is the individual most intimately and directly concerned, the one whose action we wish to stimulate.

Having chosen the individuals who make up this primary audience in any campaign, the next step is to map out their convenient group affiliations. In what organized groups can we find them? Does the prospective mother belong to clubs? Are the fathers and mothers of diphtheria-age children members of any groups? If we can honestly answer "yes," then the solution is enormously simplified. Unfortunately, we often have to answer "no," especially when it comes to prospective mothers and mothers of preschool children. Here the individual approach may be the only inclusive method.

By the individual approach I mean direct contact with the individuals making up the primary audience, with no reliance upon intermediate agencies. For instance, in the campaigns for the promotion of breast feeding that are being carried on by the Bureau of Child Hygiene and Public Health Nursing of the Michigan Department of Health, the path to the mother is direct. The nurse gets from the county clerk the names of parents of babies under 6 months, or under 1 year if a more thorough canvass can be made. She then visits those mothers. In this case the message is delivered directly to the primary audience, and to every member of it.

A variation of this method can be illustrated by the preparation for preschool clinics. A plan of carefully districted home calls can be delegated to a group, such as a mothers' club or a parent-teacher association. This is simply utilizing a group in the individual approach.

Having selected our primary audience and mapped out its group affiliations, the next step is to determine the agencies, individuals or groups that are not personally concerned in the objective but are necessary to the setting of the stage—for after all, most of our health campaigns need stage setting. There is no object in creating a desire for action unless there is a reasonably easy outlet. And to limit our selection of audiences to those that are provided with that outlet is hopelessly to limit our campaign.

There is no point in urging parents to take their children to a physician for toxin-antitoxin in a school where half of the parents cannot afford the treatments, or in a community where there is only one elderly physician and he does not take any stock in new-fangled notions. No particular gain is made when we urge regular medical care during pregnancy, and our prospective mothers live in the plains coun-

try far from a doctor. When we select our audiences we should take care that we either choose those that have the facilities for action at their command, or that we provide such facilities.

The groups and individuals to whom we appeal in this matter of providing the necessary background for action we can term our subsidiary audience. In our diphtheria prevention campaigns we enlist the physicians so that the technical side may be cared for. If the campaign is to be a community venture, with the treatments free to all children, we appeal to the groups who direct or at least influence the expenditure of public funds. We ask the support of the school authorities so that our clinics may be held in the schoolhouse and announced through school channels. We reach the groups who furnish the leadership in public sentiment.

These assisting audiences may or may not include the members of our primary audience. They are chosen on the basis of community leadership rather than immediate contact with the objective. In terming them subsidiary audiences and mentioning them last, I do not in the least minimize their value. They are often the first audience to be approached, and the deciding factor in making possible the whole campaign.

When we have selected our primary audience, found out its affiliations, and chosen our assisting agencies, we have a reasonably clear picture of our composite audience. We are struck at once by the overlapping. I have talked of groups as though they were neat pigeonholes for people, and as though people stayed in their pigeonholes, which is, of course, not true. With our present maze of organizations there is bound to be overlapping, and it is wasteful only when it is duplication. If our material is carefully sifted and prepared, it will reinforce itself by being presented from different angles. Overlapping is not necessarily a drawback in the choosing of audiences.

SUMMARY

The audiences in any publicity campaign are defined automatically by the objectives of the campaign, and limited arbitrarily by the director.

The primary audience is made up of the individuals directly involved, considered as individuals or as groups.

The subsidiary audience consists of the assisting individuals and groups, chosen on the basis of civic leadership.

A thoughtful selection of our audiences, and limitation, in the interest of thoroughness and permanence, aid tremendously in the success of the campaign.

Volatile Solvents Used in Industry*

THE danger to workers in the application of coatings to surfaces of all kinds must be considered under two heads: the character of the coating, and the method of application.

The term " lacquer " is technically applied to a coating which has nitrocellulose as its most important constituent. The solvent is an ester, amyl, butyl or ethyl acetate; and the thinner an aromatic, benzol, toluol or xylol. Castor oil or some other oil may be added as a plasticizer. Normal butyl acetate, with some normal butyl alcohol, is the solvent chiefly used, amyl acetate being more expensive, ethyl acetate less efficient. It is not really necessary to add benzol or any aromatic, but it is cheaper since butyl acetate costs about $1.25 as compared with $.30 for toluol and $.20 for benzol. These last act as solvents as well as thinners up to a certain point, beyond which they begin to precipitate the nitrocellulose. The term " varnish " is technically restricted to a coating made by dissolving a natural gum or resin in a mixture of oil and hydrocarbon.

Next to lead, the most important toxic substance used in coatings is benzol, and here a great improvement has occurred during recent years, due largely to the work of the Benzol Committee of the National Safety Council which, in its final report, laid stress on the danger of even small quantities of benzol in the air of workshops, and urged manufacturers and master painters to substitute toluol, xylol, or the petroleum distillates. This recommendation has been followed by many industrialists, and the use of benzol in coatings is more and more restricted each year. It is still to be found in some lacquers used for spraying because of its volatility. Brush lacquer calls for solvents less volatile than spray lacquer because brush work does not require such quick drying. Indeed, if it dries too quickly, edges and streaks appear. According to one expert, toluol and butyl acetate make a better solvent for spray lacquer than benzol, because the latter evaporates too fast and causes " blushing."

It is certain that in the painting of electrical or agricultural machinery, and in many automobile factories, benzol is no longer used. Varnish and paint removers still contain benzol, but in these as in penetrating stains efforts are being made to find a substitute. In

* Report of the Committee on Volatile Solvents, presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

protective coatings, little benzol is used except in fabrikoid and patent leather. In roofing compounds and tar paints, tar oil is now used.

Fabrikoid, artificial leather, or textile leather, is made by spreading over fabric a nitrocellulose coating containing benzol, sometimes in large quantity (as high as 60 per cent, according to L. Greenburg). Patent leather manufacture is similar except that the coating is spread on skins and hides. In these two industries, benzol still holds its place as solvent and thinner because it evaporates more quickly than toluol. The coating may be spread by a machine similar to that used in the manufacture of spread rubber goods, or applied with a stiff brush, or pressed into the surface with a broad knife. In this hand work, the men must bend over the skin or fabric, and it is hard to see how exhausts could be so placed as to protect them, for it is difficult to provide even window ventilation without setting up drafts which might deposit dust on the coating and spoil it. This is especially true of patent leather, where the slightest blemish shows.

Hunter and Hanflig, 1927, published reports of 6 cases of severe chronic benzol poisoning, 2 of which were contracted in making patent leather.

In making sanitary cans benzol-rubber sealing compound is being replaced by rubber latex. Other occupations in which latex is displacing benzol-rubber are: making cord fabric for tires; cementing shoes, both rubber and leather; and making dipped rubber and spread rubber goods.

Toluol is displacing benzol in nitrocellulose coatings and lacquers, while naphtha, or the less volatile petroleum distillate "Stoddard's Solvent," has largely displaced it in dry cleaning. Several state organizations of the painters' union have carried on successful agitation against the use of benzol in quick-drying paints and other coatings.

Benzol is still generally used for coating patent leather, and sometimes artificial leather; sealing bottles; fastening rubber heels on leather soles; tire building; and as a constituent of paint and varnish removers; but it is believed by insurance men and by many industrialists that in these processes also substitutes will eventually be found.

Wood alcohol is not used as a solvent except as a constituent of denatured alcohol. The formulas for denatured alcohol permitted by the U. S. Treasury Department were revised in February, 1928. The one most largely used for coatings of all kinds is Specially Denatured Formula No. 1, 5 gallons of wood alcohol to every 100 of ethyl alcohol. Other permitted formulas used for varnishes, japans, lacquer thinners and lacquer solvents, are No. 2A, which has 2 gallons of wood alcohol and 2 of benzol to 100 of ethyl alcohol; and No. 23A,

with 10 gallons of acetone and 2 of benzol to 100 of ethyl alcohol. Denatured alcohol, therefore, as used in the coating industry, contains only a small proportion of wood alcohol.

In the study made by the German Association for Industrial Hygiene, several less familiar solvents are mentioned as being used in nitrocellulose coatings. The less volatile but more toxic cyclohexanol acetate may take the place of butyl acetate, and the place of a ketone, usually acetone, may be taken by carbon tetrachloride, chloroform, tetrachlorethane, or trichlorethylene. These solvents are of little or no importance in the United States. Trichlorethylene is not used in coatings such as paint and varnish; tetrachlorethane is not important because cellulose acetate, for which it is the best solvent, is too expensive, and our lacquers are made with nitrocellulose. Chloroform is not used in coatings in this country, and carbon tetrachloride very little. The solvents chiefly used in the United States are normal butyl alcohol and the acetates, amyl, ethyl, and normal butyl. Among new American solvents are ethyl oxybutyrate and the methyl ester of ethylene glycol known by the trade name " cellosolve " and referred to in the 1928 *Chemical Engineering Catalog* as ethylene glycol monoethyl ether. Both of these are advertised as non-toxic, but master painters report that men using them complain of dry throat, feeling of tightness in the chest, and " dopiness."

The Pennsylvania survey, under the direction of Henry Field Smyth, M.D., made some preliminary toxicity tests on guinea pigs by exposing them in Yant and Frey gassing jars to the vapors of two of the above solvents, and the authors have since made similar tests with all of the others, except benzol, that were reported as present in 5 or more lacquers in the Pennsylvania questionnaire, as well as on one type of turpentine, a solvent sometimes found in the newer, less rapidly drying brushing lacquers. They also included distillates obtained from a spraying and a brushing lacquer, both containing less than 0.5 per cent of benzol.

Keyes divides the usual fluid components of lacquers into four groups, based primarily on their boiling ranges:

1. Low boilers, boiling below 100° C., with benzol as the type. In this group are found, among others, ethyl acetate and ethyl alcohol. They usually comprise 10 to 25 per cent of the liquid portion of spraying lacquers.

2. Medium boilers, boiling near 125° C., including toluol, amyl acetate, butyl alcohol and turpentine. They usually comprise 20 to 45 per cent of spraying lacquer liquid.

3. High boilers, boiling from 150° to 200° C., including xylol. High flash naphtha or heavy gasoline would come in this group. They usually comprise 4 to 10 per cent of spraying lacquers, but would form a larger percentage of brushing lacquers.

4. Plasticizers, boiling above 200° C., and not included in the above list, as they are non-volatile at ordinary temperatures and are used in small amounts only. Therefore, they are not a potential menace to the sprayer as ordinarily used.

In applying the coatings, the use of the spray gun has increased and seems destined to keep on increasing. It is said to be wasteful of paint but more than makes up for this by the saving of labor and the speed. The painter still clings to brush work for varnish and to a certain extent for paint, but lacquers are universally applied by spraying, and are displacing both paint and varnish. A large proportion of paint is also applied by spraying. For automobiles, electrical machinery, railway cars and agricultural machinery, spraying has supplanted dipping and brush work. This means a greater hazard to the painter, but this has been compensated for in part. The paint now used is more often than not lead free; the dangerous work of dry rubbing down lead paint has almost disappeared in all but high grade interior work; the devices for protecting the operator are improving as the construction and forced ventilation of spraying booths and the pressure in the spray gun and its construction improve. The pressure is now sometimes as low as 20 pounds, whereas 60, 80, and even 100 pounds were general formerly.

Pouring the paint or flowing it from a hose is in use in some large shops manufacturing electrical equipment. It is, on the whole, the method least attended with risk to the operator, since he stands at a distance and does not come in contact with the paint at all, nor does he need to be protected against pollution of the air from atomized paint.

ALICE HAMILTON, *Chairman*
ELIZABETH B. BRICKER
HENRY FIELD SMYTH

DISCUSSION

P. W. Gumaer, Barrett Company, New York, N. Y.—In reference to the use of benzol it must be pointed out that substitutes such as toluol often cannot be used, since it is a by-product of coal tar distillation produced in small amounts only. The producers are fully alive to the health hazards, and are going far to educate in the safe usage of such substances. Do we know what benzol poisoning is? I am not a physician, but does a low white cell count always mean benzol poisoning? If I am not mistaken there are a number of other conditions unassociated with benzol which may show a low white count. As with lead poisoning, we must have standard diagnostic methods before we can control this hazard and the public concern about it. It is my special province in the company with which I am connected to develop safe procedures for the use of this indispensable product, benzol.

Tentative Record Forms for School Health Work*

School Health Record Form 2

THE form here presented is designed for schools which have medical personnel available for the examination work. This differs from Form 1,† which is for schools having no medical assistance.

Form 2 is designed to bring together in a simple and compact manner those facts about the health of the child which the school can use most advantageously in the child's interest.

Four main groups of facts are called for; namely, (1) communicable diseases and certain other important ailments experienced, (2) immunization record, (3) record of physical examination, and (4) record of absences by cause.

The facts on communicable diseases are of value in guiding administrative action when such diseases are prevalent and it is important to know which children are susceptible and which are immune. The facts on immunization supplement the above record. The physical examination record is needed to assist the school in understanding the child and in guiding his educational program intelligently. The absence record likewise is necessary to a proper understanding of the child. These facts are not ordinarily called for and they constitute a new feature on the school health record. They are inserted here because they are believed to be a potential source of valuable information which has hitherto been greatly neglected.

One difficulty in preparing such a chart is that it presumes certain uniformity in procedure. With varying laws, regulations, organization and personnel, it is quite impossible to devise a single procedure that is best for all places. The committee recommends this card as it stands, conscious that certain adaptations may be necessary to meet differing local situations.

The card shown here is a standard 5″ x 8″ card, Index Bristol, with the entire record on one side. The reverse side can be used for the

* Report of the Sub-Committee on Record Forms (prepared by George T. Palmer, and recommended for experimental use), presented to the Committee on Administrative Practice of the American Public Health Association at its meeting, May 22, 1928.

† Form 1 was published as the pamphlet *Record Forms for Public Health Work*, September, 1927, American Public Health Association, 370 Seventh Avenue, New York, N. Y.

continuous educational record, the local form for which may be printed thereon, or the reverse side may be used for important supplementary notations. It is not intended that the reverse side shall carry the detailed records of home visits by the nurse. This card is to be kept with the teacher, notations on it being made by teacher, nurse and by or for the physician.

Space is provided for the recording of the routine examination findings in terms of a code shown on the card, at three periods during the school life of the child. Preferably these three periods would be the first grade, fifth grade and just before the age when a child is permitted to leave school and secure working papers.

While, from administrative considerations, more than three examinations during elementary school life are not recommended as a routine for all children, it is of course understood that special examinations at more frequent intervals may be quite necessary for certain children.

In mapping out the medical inspection program, time for these special examinations should be taken into account. The routine inspections should not be permitted to take up all available time. Quality of school medical work as well as its utility in the administration of the educational program must not be made to suffer merely for the sake of greater volume.

The value of the medical inspection is at least three-fold: to make available to the educational authorities facts to assist them in planning a course of instruction best adapted to the capabilities of the child; to serve as a demonstration to the parents of the value and utility of professional medical opinion; and, as an outcome of this, to assist the child early in life in eliminating physical defects which may seriously impede his learning and living efficiency. For these reasons it is recommended that every effort be made to secure the attendance of one or both parents at the examination, particularly that made while the child is in the first grade.

One other point should be emphasized. The physician by his training and experience possesses a superior knowledge of anatomy and physiology, and symptomatology of health and departures from health. Consequently his judgment should be utilized to maximum advantage. His time should be conserved and he should be freed from any routine procedures which can be handled with equal satisfaction by one less experienced. Whenever possible the nurse should assist and lighten the physician's burden. The routine inspection of vision and hearing in so far as it is meant to reveal outstanding deficiencies is a matter that is capable of being reduced to a mechanical procedure, the results of which are just as informing under practical

school conditions when carried out under the physician's supervision by nurse or teacher as if done by the physician himself. Doubtful or special cases may very properly be referred to the physician. It is also an economical step to spare the physician the labor of recording his findings on the card. This might better be done by a clerk or, if this is not feasible, by the nurse.

Success in correctly marking the various items called for in the inspection and in securing the alleviation of defects depends so largely on the proper synchronizing of interests of physician, nurse, teacher and parent, that the association of these individuals should be a definite goal on the part of the school administration.

The card is to go with the child as he passes from grade to grade. To be of maximum service all possible information should be recorded when the child enters school, and the other information added from time to time.

INSTRUCTIONS FOR MARKING RECORD FORM

(Record in ink)

Name—The name can be written with the given name first or last, it is immaterial.
Sex—Use M for males, F for females.
Color—Use W for white, B for black.
Birth Date—This is recorded most simply by figures. Thus, Oct. 17, 1915, would be 10/17/15.
Parent or Guardian—Write name.
Addresses—Several lines are left for addresses as well as date when new address was recorded.

36 Cypress St.—9/16/25
1320 Oxford Place—1/6/27

Diseases—Year—Record the year when the child has the disease indicated or when the ailment was first noted. This entry should be made out as completely as possible when the child enters school, the facts being ascertained by sending a note home to the parents, or it may be more convenient to question the parent when she or he is present for the first examination. There may be some slight error if it happened that there was no physician in attendance at the time of the child's illness. However, these diseases are quite distinct and are usually events well remembered in most households. If this record is made with care, it will prove most serviceable to the teacher later. When measles breaks out she will know by the record what children will probably not have it because of previously having had it, and she will know those who are apt to contract the disease following exposure to active cases. If a child contracts any of these diseases at a later period during school life, the age should be entered by the teacher at that time.

If Tb in Family, who (relation)—This information should be secured from the parents direct or by note. Record "sister," "brother," "father," etc. Knowledge of the fact that there has been or is tuberculosis in the home should make the teacher doubly watchful of the school pupil from that family.

Immunization—The really important facts are to know whether the child has received the complete series of three inoculations and whether a subsequent Schick test indicates that the child is immune to diphtheria. The date of third treatment can be recorded as 10/16/30, meaning October 16, 1930. It is assumed that the details of the first and second inoculations will be kept on a sheet by themselves and that only the final record will be made on this permanent record card. Record age to nearest year. Give the date when the Schick test indicates that the child is immune from diphtheria. Record in figures as 10/19/32.

If a child entering school at 6 years of age was vaccinated successfully when 3 years of age, record the approximate date as 10/—/24. This example assumes that the exact date is not known but the month and year are. Record age to nearest year when the last successful vaccination was given.

If a child is vaccinated again when 9 years of age, record the date as 4/16/32 and underline the word which indicates the result, namely, whether the vaccination was positive ("a take") or negative (no reaction), or showed an immunity reaction, a reddened area for several days which clears up without the formation of the blister or pustule.

The knowledge that pupils are not susceptible to certain diseases either because of immunization or from having had the disease itself will prove of value to the school authorities.

Physical Examinations—Space is purposely limited here in order to encourage the more thorough but less frequent examination. The longer interval between examinations is recommended in order to discourage the superficial character into which annual examinations so commonly have fallen, and to save the time and labor entailed in the acquiring of great masses of records of which but little use can be made because of the inadequacy of the staff for the purpose in the average school.

Grade—Record school grades as I or V. (Roman numerals.)

Date—Record in figures as 10/13/27.

Parent Present (yes or no)—Write yes if parent or guardian was present at the examination; no, if not present.

Nutrition—Grade in terms of the scale shown, 0—meaning good nutrition, 1—fair, 2—poor, and 3—very poor. This grading is in general terms and rests upon the opinion of the physician. As soon as more exact standards for rating nutrition are available they should be utilized.

Height—Record to nearest inch, children being measured without shoes.

Weight—Record to nearest pound, sweaters, coats and extra wraps of course being removed. (Weight should be with ordinary indoor clothing.)

Standard Weight—Record to nearest pound, taking figure from Wood-Baldwin height-weight-age tables or other more accurate tables when available.

Per cent Deviation + or — —Record in round numbers after computing per cent above or below standard, thus — 6 or + 10.

Posture—Record in terms of the scale. The examiner's judgment must determine the ranking. When nationally accepted standards of rating posture are available they should be used.

Teeth—Record in the general terms of the scale.

Nose-Throat—Record in terms of the scale; the decision being made on the history

(see Recurrent Tonsillitis and Rheumatism at top of card) in conjunction with what is visible from the direct examination.

No separate columns are provided for tonsils or adenoids or mouth breathing or enlarged cervical glands. A specialist to whom the child may be taken by parents will, of course, make his own deductions and it is sufficient in the school examination merely to direct general attention to this area.

Special care is advised in marking this item. There has developed a tendency to mark tonsils on appearance alone. This is a questionable procedure. Something of the history as well as size and appearance should be obtained before definitely designating a defect. Where this is difficult to obtain, and yet the appearance of the tonsils is unfavorable, it is recommended that the symbol 1 (slight) be favored in preference to a 2x. The designation of 2x sets in motion a chain of events involving expense and is also capable of creating misunderstanding between the school physician on the one hand and the parents and family physician on the other. It is true that the child's welfare must not be neglected in the effort to prevent misunderstanding. At present, however, it would seem that tonsil defects are magnified, over-emphasized and reported too freely rather than the reverse.

The experience of teacher and parent will be helpful in detecting adenoids or mouth breathing. Likewise the child's absence records from colds (at the bottom of the card) will be helpful in the later examinations.

Heart—Record in terms of the scale. Unless it is permissible to bare chest and back to make the stethoscopic observation this item should be omitted. An inspection that is so superficial as to be without significance is not justified.

Where suspicious signs are present, a test for rate of pulse recovery may also be made.* The experience of teacher and parent with the child's actions may also be found helpful in supplementing the evidence the physician is able to get directly.

Vision—Record in terms of the scale. It is presumed that the Snellen or equivalent test for visual acuity will be used. If a defect is indicated in either eye, it should be noted. It is not necessary to show on the card the rating of each eye independently. The ophthalmologist who later examines the child will draw conclusions from his own examination, and further detail in the routine school examination will not be necessary.

Hearing—Record in terms of the scale. The whispered voice test is probably used most commonly. The use of the audiometer with which an entire classroom may be tested at once is recommended where the volume of work is such as to warrant the expense of the instrument. This is manufactured and sold by the Graybar Electric Co., Graybar Building, Lexington Avenue and 43d Street, New York, N. Y.

Thyroid—Record in terms of the scale.

Other—Note here any other outstanding matter of importance not already listed.

General—The back of the card may be used to record special details in connection with the examination if this is desired.

It is recommended also that supplementary instruction sheet be prepared locally to help interpret the meaning of the code terms—" slightly," " moderately," " markedly " unsatisfactory. Thus, in the case of vision, it might be explained that inability to see the 20/20 line but yet reading the 20/30 line would be marked 1. Reading the 20/30 but not 20/40 would be marked 2 and inability to read 20/70 line as 3.

---

* See procedure in Pittsburgh schools, Dr. Harry Burns, Medical Director.

The Marking Code—The scale for marking shown on the card is largely self-explanatory. Its use is advised for the sake of uniformity and understanding. The grading marks 1, 2 and 3, will, of course, vary with the subjective impressions and diverse methods of individual physicians. As rapidly as reliable standards are developed they should be utilized.

Mark 2 " present," implies a condition more marked and positive than 1. An item marked 2 — should ordinarily be referred to the family physician for further medical advice. However, there are instances where it is inadvisable to follow up this condition with home visits by the nurse. For that reason the character x is reserved as a follow-up symbol, a signal for the nurse to " go ahead " with the case.

Mark 3 is reserved for conditions demanding special or immediate attention. Almost invariably an x would appear with the 3. The special marking of certain cases with a 3 enables the nurse to give them precedence in mapping out her visiting schedule.

Where there has been a previous correction, use the symbol 00, which indicates something different from normal but still not necessarily a defect.

Use — to indicate information sought but not obtained to distinguish from a blank space which would indicate no information sought.

If no mark is made, and the space is left blank, succeeding teachers will be puzzled to know whether the result was negative or whether no observation was made. The maximum value of this card to succeeding teachers is the completeness of the record which comes to them. If it is incomplete, succeeding teachers will not be inclined to place dependence on the record.

N—is a symbol to indicate that the family has been notified of the findings.

/—A diagonal line from lower left to upper right corner of square, and through the defect record, indicates that the school examination was not verified by the family physician.

×—A cross over the entire space, made over the record of a defect, indicates that the matter is receiving professional attention.

These last two marks would represent a termination of the case for that individual item, so far as the nurse is concerned.

The uncrossed off x's represent the remaining work for the nurse.

Absence Record—In the lower part of the card is space for noting the absence record. There are wide columns for each of 7 school years. These columns are divided into two parts, so that absence for each term may be recorded.

The entries in this space are to be made at the end of the term. They represent the summation of the daily experience. They are taken from the Class Room Register on which must be kept the detailed cause of absence in terms of the code indicated on the card.

On the Class Room Register, in place of marking an A for absence it is recommended that a dot (.) be made. When the child returns to school with an excuse or the cause of the absence is otherwise determined, the teacher can then write on top of the dot the appropriate letter indicating the class of absence, whether C, D, S, E, M. As described in succeeding paragraphs all absences can be recorded under one of the five headings. The groups are distinct and their titles self-explanatory and mutually exclusive and the designating letter is purposely made suggestive.

At the end of the term the numbers of each letter showing on the register can be totalled and recorded on the health card.

While this practice involves slight additional work, the securing of accurate information as to the amount, nature and location of illness enables the teacher to understand better the causes of absences, and this in time is of assistance in promoting health and preventing illness. This is as definite a contribution as the discovery and elimination of physical defects.

School Year—Record the years the child has been in school. Thus the child may be in the third grade but, having at some time repeated a grade, this is really his fourth school year.

Name of School—Designate school by name or number.

Grade and Age—Place grade number above, and age in years below, the diagonal line.

Number Registration Days for Child—This is entered for each term. This number may differ somewhat among the children of the class as some children may have entered school after the beginning of the term.

Absence—Total Days—At the end of the term, record here the total days absent. Count half days absence as one-half.

The entries C, D, S, E, M are subdivisions of the total and their sum should equal the total. The purpose of the subdivision is to convey to subsequent teachers the nature of the absences, for these have differing health significance. Twenty days' absence is not of health significance if due to absence from town on a visit, or to exclusion from school not because of the child's illness but because of exposure to another child with some communicable disease. This information on sickness and its nature will prove of value to subsequent teachers in their dealings with and understanding of individual children. The summation of these causes of absence by room and by schools will also be of value to principals and superintendents administratively.

Entries by cause—C, D, S, E, M.

Five distinct classes of absences are recognized, viz.:

(C) Colds and Sore Throat
(D) Disease, Communicable (specific infections)
(S) Other sickness
(E) Exclusion because of exposure to Communicable Disease
(M) Miscellaneous Causes, not sickness of the child

(C) *Colds and Sore Throat*—Under the heading (C) record colds, sore throat and complications associated with colds such as tonsillitis, bronchitis, laryngitis, pharyngitis, influenza, pneumonia.*

(D) *Disease, Communicable*—(so-called diseases of childhood)—This refers to specific communicable disease for which isolation or quarantine are prescribed, such as measles, mumps, chicken pox, whooping cough, German measles, scarlet fever, diphtheria, typhoid, poliomyelitis, smallpox. It also includes transmissible infections such as impetigo, scabies, ringworm and pediculosis.

(S) *Sickness*—(symptomatic, including injuries)—Include here all other sickness not covered by the two items above. For instance, headache, stomach ache, toothache, broken arm, burns, etc.

(E) *Exclusion, Exposure to Communicable Disease*—This is reserved for those absences which are enforced by the school in order to protect other pupils. In this case the child is not ill but is kept from school because of a known exposure to a case of communicable disease. If the child thus excluded contracts the disease,

* Influenza and pneumonia are arbitrarily placed under this heading even though there is good reason for including them under D.

the days' absence following the diagnosis of the disease should be recorded in the register as (D).

(M) *Miscellaneous causes not illness of the pupil, other than above*—This designates absence to go shopping or visiting, to see the oculist or dentist, or to stay at home with a sick parent, or to mind the baby, etc. In other words, the child is not ill, nor is he kept from school because of exposure to communicable disease. This type of absence may account in some instances for one-fifth to one-half of all absences and in epidemics has been known to go as high as 90 per cent of all absence.

The Problem of Finance in Rural Health Practice*

DOUGLAS L. CANNON, M. D.

Assistant State Health Officer, Montgomery, Ala.

THE governor of Alabama, on September 27, 1923, approved an act of the legislature making available $55,000 as a state-aid fund for county health work. This sum was sufficient at that time to subsidize 22 counties not in a position to carry the entire burden of providing health service for their people. Participation in the fund was made contingent upon the appropriation by a county of a sum of money sufficient to secure a permanent health organization and adequate to do effective work, the amount in each instance to be determined upon the advice and with the approval of the State Board of Health. A further act of the legislature, approved August 26, 1927, provided a subsidy of $2,500 per county for all counties not already receiving state funds for local health work, on condition that these counties make available an appropriation in accordance with the terms specified above.

When the organized counties numbered 33, October 1, 1927, the State Board of Health was aware of the fact that of the 34 counties not then receiving full-time health service only a very few were financially able to make the minimum appropriation of $5,000 theretofore required in order to participate in the county organization fund. On the other hand, among the 34 were a number urgently in need of a well planned and continuous program of health preservation and disease prevention. Therefore, to arrive at a figure that even the poorest counties could meet in order to enjoy the benefits of the fund, two plans suggested themselves. The first was on the basis of the per capita appropriation being made by those counties essentially like the group remaining to be organized. There were 21 such counties, no one of them with a municipality exceeding 10,000 population, the majority without a municipality in excess of 5,000, and 9 altogether rural. This study revealed the average per capita appropriation to be 17.75 cents. The range was from 10.49 cents to 24.15 cents.

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

When the average was applied to the populations of the existing unorganized counties it was found that the appropriations which the State Board of Health might have a right to expect varied from $2,360 in the least populous county to $6,354 in the most populous. The results were not altogether satisfactory. In most instances they represented a need for health work rather than ability to pay. Knowledge of local conditions and character of population justified this conclusion.

It seemed advisable then to determine what the per capita appropriation would mean in terms of tax rate, the assessed valuation of property in the several counties as given in the latest report of the State Auditor being used as a basis. The study of this relationship showed that an appropriation could not be calculated solely on the basis of the average per capita as determined for the organized counties.

To proceed upon such a plan would mean that the appropriation of County A would be equivalent to a tax rate of 7.46 cents per $100 of property as assessed; that of County B, 7.09 cents; County C, 7.75 cents; and of County D, 7.21 cents. Obviously such rates were too high.

The question then arose as to what would be a reasonable rate to apply. To arrive at a solution (the second plan), the average appropriation in cents per $100 of property as assessed, in the group of organized counties used above, was determined. The average was found to be 4.95 cents. To avert criticism from the organized counties that less was being expected of the unorganized—$5,000 having been the minimum amount theretofore approved by the State Board of Health if a county participated in the county organization fund—it seemed wise to exceed the average in arriving at the ideal rate.

How far above the average, though, should the ideal be? It was known, for example, that several of the organized counties making an appropriation approximating 6.5 cents per $100 of assessed property found it difficult to meet the appropriation. Somewhat arbitrary reasoning then seemed to indicate that the ideal should lie between 4.95 and 6.5 cents. As a trial procedure, 5.5 cents was chosen. When this was applied to the property assessments in the unorganized counties, a given county's appropriation of $2,360 on the per capita basis became $1,765 on the property assessment basis, a greater difference than might be apparent without the knowledge that the population of the county in question is 13,300 and the assessed property but little more than $3,000,000. In the case of a second county, $6,354 became $6,152, a negligible difference because the county has property assessed in excess of $11,000,000.

COMMENTS

The Alabama State Board of Health is of the opinion that adequate service cannot be rendered by a county health department that has a smaller personnel than 3, or an annual budget of less than $7,000. Of this amount the State Board of Health is in position to contribute $2,500 from the county organization fund. Unless an arbitrary standard of coöperation is adopted, with the state bearing much the larger share of the burden, it would remain for a county to make a minimum appropriation of $4,500.

The study made of the ability of the unorganized counties to pay for health service revealed that only 7 of the 34 could attain this figure. If, therefore, these less fortunately situated counties are to receive approved health service, means must be provided to care for the deficit after the county organization fund and the local appropriation have been made available.

An equalization fund is not unknown in the operation of certain departments of state government. It should not be unknown in the operation of a health department. State-wide health service, at least in the South, can hardly be attained unless such a fund is set aside to aid counties as equally deserving as others but not able to make more than a small part of the total appropriation needed for adequate protection. Fortunately Alabama has been able to have the equivalent of an equalization fund. This has been made possible through the use of a portion of the money appropriated by the legislature for the general operating expenses of the State Board of Health, together with subsidies from extra-state agencies. When these extra-state subsidies have been withdrawn, an equalization fund must become a reality by legislative enactment.

Finally, the problem of finance, if initially acute, is likely to remain acute over the second and third years of the county health department's life. Normal expansion of work must be provided for. Adequate salary increases must be granted, if stability of organization is to be maintained. To assure these there must be an annual increase in appropriation, certainly after the second year. The source of the added revenue remains to be determined, but sound administrative policy would seem to direct that it be derived from county funds.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

EDITORIAL COMMITTEE

MAZYCK P. RAVENEL, M.D., *Chairman* HOMER N. CALVER, *Managing Editor*

C. C. YOUNG, LOUIS I. DUBLIN, PH.D., E. R. HAYHURST, M.D., MERRILL E. CHAMPION, M.D., ARTHUR P. MILLER, C.E., HENRY F. VAUGHAN, D.P.H., EVART G. ROUTZAHN, C.-E. A. WINSLOW, DR.P.H., WALTER S. FRISBIE, SOPHIE C. NELSON, R.N.

THE HEALTH OFFICER'S TENURE OF OFFICE

IT IS not possible to prevent completely all changes in the personnel of health departments, either local or state. Our "In Memoriam" resolution at the Chicago meeting included the names of forty members who had died during the year, of whom fifteen were health officers or health commissioners. Since all health officers are not members of our Association, the actual number of health officials who died is probably considerably in excess of fifteen, death causing a number of vacancies which must be filled.

In addition, quite a number of officials return to the practice of medicine or take up some other work which promises freedom from political interference and worry, or more adequate financial returns, better prospects, or some other advantage of sufficient weight to bring about a change in vocation.

Many health officials have been removed because of a change in the dominant political party or through some supposed indiscretion. There are some such cases on record which remind one of the rise and fall of court favorites in Europe in the 17th century. This statement is not made to justify all acts of health officers. Being human, they are capable of error, and, like other people, often make mistakes. In some cases their removal has been justifiable, but in others it has not.

Time is an element in success in health work, and the tenure of office of the average health officer is altogether too short. A report made last October showed an annual turnover of health officers amounting to 14 per cent. This must have meant the slowing up of work, or disturbance of programs for betterment, in many communities. Uncertainty of tenure is apt to cause hesitancy or unwillingness on the part of the health officer to launch a program requiring time for its accomplishment. When the officer is reasonably sure that his ten-

ure of office will be brief, it is almost certain to interfere with his activities and to make him doubtful of the wisdom of initiating measures which require the longest possible period of time for their accomplishment.

The Executive Board of our Association recently sent the following significant message to one of our governors:

The American Public Health Association has long recognized that the security of health protection to the people, the continuity of constructive health programs, and the efficiency of the service are seriously hampered by the frequent shifting of the administrative head of the health department. The Association has also found that where the employment of the administrative head or health officer is in the hands of a board of health or council of members interested in public health, appointed for overlapping terms, sound policies have been established and effective service continuously rendered. For these reasons the Association through its Executive Board urges that you take steps at an early date to assure to the people of your state the benefits of such a policy.

In the instance which brought out this resolution, a change in the office of health commissioner was unavoidable, but we are glad to say that the new appointee was a physician who had had wide experience as a health administrator, and who will, with little or no break, continue the policies and programs so successfully adopted and pushed by his predecessor. We wish that all changes in state health officers could be accomplished with as little disturbance and detriment to the welfare of the people as in this case.

YELLOW FEVER AWARDS

NEARLY 28 years after the demonstration of the agency of the Stegomyia (*Aëdes aegypti*) mosquito in spreading yellow fever,[1] the Congress of the United States has finally given official recognition to this great piece of work and provided a pension of $125 a month to the 16 of those now living who took part in these dangerous experiments, and to the widow of one. In addition, a gold medal will be given to each of the living and to the representatives of those now dead.

The Yellow Fever Commission consisted of Walter Reed, James W. Carroll, Jesse W. Lazear and Aristides Agramonte. Dr. Lazear died of yellow fever after having allowed himself to be bitten by a mosquito. Dr. Carroll, who also allowed himself to be bitten, was seriously ill, but recovered, though some remaining disability is believed to have played a part in his death later. Dr. Reed did not contract yellow fever, and died of appendicitis some years after his return to the United States. Dr. Agramonte, who was an immune, is the only member of that famous Commission now living.

The story of their work has often been told, but cannot be too often repeated. Only those who have lived in those parts of the country formerly visited more or less frequently by yellow fever can appreciate what the disease meant in terror, human suffering and financial loss through interruption of commerce. Fumigation directed toward the extermination of insect carriers is now employed instead of the former disinfection intended to kill the supposed germ. Our ports are now open to ships from any part of the world throughout the year. No longer are vessels tied up at quarantine for weeks and months. Never again will yellow fever be epidemic in any city of our country. The benefits of the discoveries of the Yellow Fever Commission have been extended to every part of the world in which the disease has existed. Its work has been recognized by scientific men everywhere, and abundantly confirmed, not only by foreign commissions, but also in practice.

We rejoice that Congress has finally responded to the urgent representations made for years past and recognized not only the men who directed the work, but those more humble ones who offered themselves for experimental purposes. No greater courage has ever been shown in war or in peace than was displayed by these men.

We regret the necessity of introducing a discordant note, but must call attention to the miserly pittance granted to those through whose agency thousands of lives have been spared and millions of dollars saved. The richest country in the world could well afford adequate recognition of such notable services. However, it marks the beginning, and we may confidently hope that in the future similar services will be more promptly and more suitably rewarded.

We cannot close without mention of the further extension of our knowledge of yellow fever by devoted men working in West Africa, four of whom have given their lives as the price. The findings of our Army Commission have been further confirmed, and there is hope that a vaccine has been developed which will protect those carrying on such studies as well as others who may be exposed through the exigencies of their calling.

ASSOCIATION NEWS

MINNEAPOLIS HOTELS

FOR the convenience of delegates, a number of Minneapolis hotels are listed with their rates. A map appears on page 542 showing the location of these hotels and their proximity to the Auditorium, where all the technical sessions and the exhibits will be held.

It is advisable to engage rooms in advance of the meeting, and a reservation blank is printed on page 545 for that purpose.

All applications should be made directly to the hotels.

HOTEL RATES

Hotel	*Address*	*Room Capacity*	*One Person*		*Two Persons*	
			With Bath	*Without Bath*	*With Bath*	*Without Bath*
Curtis	10th St. & 4th Ave. S.	825	$2.00–3.00	.....	$3.00–6.00	.....

NATIONAL SAFETY CONGRESS

The National Safety Council and the American Public Health Association meet this year in the same week, the former in Chicago, the latter in Minneapolis. As Chicago is en route to Minneapolis, it will be possible for physicians and public health workers interested to include sessions of the National Safety Congress in their week's program. The medical sessions of the National Safety Congress come on Monday and Tuesday, and possibly Wednesday, whereas the A. P. H. A. Industrial Hygiene sessions in Minneapolis will take place on Thursday and Friday.

DR. BISHOP HONORED

E. L. Bishop, M.D., Commissioner of Health, Nashville, Tenn., Secretary of the Health Officers Section, A. P. H. A., has been appointed a member of the Board of Scientific Directors of the International Health Division of the Rockefeller Foundation. The other members of the board are: F. F. Russell, M.D., General Director of the International Health Division; Rufus Cole, M.D., the Rockefeller Institute; Louis I. Dublin, Ph.D., the Metropolitan Life Insurance Company; Wade H. Frost, M.D., Johns Hopkins School of Hygiene and Public Health; W. G. Smillie, M.D., Harvard School of Public Health; and C.-E. A. Winslow, Dr.P.H., Yale School of Public Health. This group will give expert advice concerning budgets, policies and programs, and with regard to certain activities will serve as a special executive committee with delegated authority.

VIRGINIA PUBLIC HEALTH ASSOCIATION

The Virginia State Public Health Association held its annual meeting in Richmond, Va., February 20. The following officers were elected for the year 1929: *President,* W. B. Foster, M.D., Richmond; *1st Vice-President,* W. H. Pott, M.D., Norfolk County; *2d Vice-President,* G. F. McGinnis, M.D., Richmond; *Secretary-Treasurer,* Fred J. Wampler, M.D., Richmond; *Representative to the A. P. H. A.,* M. G. Perrow, Lynchburg.

NEW MEMBERS

Joseph M. P. Allaire, M.D., Joliette, P. Q., Health Commissioner

Harold E. Babbitt, M.S., Urbana, Ill., Professor of Sanitary Engineering, University of Illinois

William E. Ayling, M.D., Syracuse, N. Y., Health Supervisor of School Children

M. B. Beckett, M.B., Saginaw, Mich., City Physician and Assistant Health Officer

J. William Boren, M.D., Marinette, Wis., City Health Commissioner

J. Adelard Boucher, M.D., Watertown, Mass., Health Officer

Alice Britton, R.N., Charleston, W. Va., Public Health Nurse, Kanawha County Health Unit

Edward F. Brown, New York, N. Y., Director, Diphtheria Prevention Commission, City Department of Health

Ira C. Brown, M.D., Seattle, Wash., Medical Inspector, Public Schools

Joseph A. Chapman, B.Sc., New York, N. Y., Clinical Pathologist, Chapman's Pathological Laboratory

Raymond S. Crispell, M.D., Kingston, N. Y., School Physician

Jess L. Cunningham, R.N., Beckley, W. Va., Health Nurse, Raleigh County

Paul M. Drake, M.D., Coquille, Ore., Coos County Health Officer

Ashton W. Ecklund, B.Sc., Bismarck, N. D., Instructor in Hygiene and Sanitation in local hospital

Heward E. Elmer, B.S., Detroit, Mich., Bacteriologist, Owen Clinical Laboratory

Robert C. Farrier, M.D., Homer, La., Director, Claiborne Parish Health Unit

C. B. Finefrock, M.D., Port Clinton, O., Health Commissioner, Ottawa County

John S. Fulton, M.D., Emporia, Kan., County Health Officer

Beulah Gerber, Painesville, O., City and Township School Nurse

Ollie M. Goodloe, B.S., Booneville, Ky., Director, Owsley County Health Department

Arthur H. Graham, M.B., D.P.H., Montgomery, Ala., District State Health Officer

G. Webster Hallett, Osterville, Mass., Member, Local Board of Health
Charles F. Herm, Daytona Beach, Fla., Clinical Pathologist (Assoc.)
William C. Humphries, M.D., Griffin, Ga., Commissioner of Health, Griffin and Spalding County
Laura E. Jones, M.D., Syracuse, N. Y., Examining Physician, Solvay School System
Thomas Kelly, V.M.D., Philadelphia, Pa. (Assoc.)
Jonas E. King, M.D., Girard, O., Health Commissioner
Alvin Kirmse, M.D., Tucson, Ariz., City Health Officer
Richard C. Leonard, Fargo, N. D., Director, School Dental Program
Vivian E. Linden, Alhambra, Calif., Public Health Nurse, Los Angeles County Health Department
Eugene R. Linklater, M.D., Kenmore, N. Y., Health Officer
Frank E. McCord, M.D., Topeka, Kan., County Health Officer
Charlotte McLoughlin, R.N., Charleston, W. Va., Public Health Nurse, Kanawha County Health Unit
Louis Mendelsohn, M.D., Saratoga, Calif., Deputy Health Officer, Santa Clara County
Henry A. Mentz, Hammond, La., Consulting Engineer
S. C. Moore, M.D., Cadillac, Mich., Health Commissioner, Wexford County
Charles F. Neergaard, New York, N. Y., Hospital Consultant (Assoc.)
Arthur W. Newitt, M.D., Birmingham, Mich., Health Officer
Helen L. Palliser, M.D., Poughkeepsie, N. Y., Medical Inspector of Schools
Edward W. Pape, Lakewood, O., Teacher of Biology, Lakewood High School
Julius Pizzoferrato, Steubenville, O., Health Commissioner
Arthur O. Ratliff, Charleston, W. Va., Sanitary Engineer
Richard E. Reinke, B.S., Atlanta, Ga., Sanitary Engineer
Horace M. Roberson, M.D., Cleveland, Tenn., Health Officer
J. N. Rosenberger, V.M.D., Philadelphia, Pa. (Assoc.)
Henry C. Schumacher, M.D., Cleveland, O., Director, Child Guidance Clinic
C. Morley Sellery, M.D., Los Angeles, Calif., Temporary Assistant Director, Dept. of School Health
H. B. Senn, M.D., Beaufort, S. C., County Health Officer
Mrs. Romaine E. M. Smart, New Haven, Conn. (Assoc.)
Mrs. June Snell, R.N., Morgantown, W. Va., County Nurse
Mitchell B. Stock, Bridgeport, Conn., Public Health Engineer, Nustone Products Corp.
Normal R. Sullivan, M.D., Santa Cruz, Calif., City Health Officer
Louis-Rene Vezina, M.D., D.P.H., Terrebonne, P. Q., County Medical Officer of Health

DECEASED MEMBERS

Robert M. Boyd, M.D., Fort William, Ont., Can. Elected member 1926

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Making a Morbidity Survey—In 1925, J. V. DePorte, M.D., Director of the Division of Vital Statistics of the New York State Health Department, outlined a project for obtaining morbidity statistics through direct reporting by attending physicians. In 1927 the active interest of 150 physicians having been secured, a survey was commenced which lasted for 12 months. One hundred and seven physicians serving a population of about 101,000 reported 98,069 cases of sickness.

The list of causes of illness must be brief since a busy rural practitioner cannot be asked to give the time necessary to fill out a blank containing all of even the more important types of sickness. The subdivisions were limited to sex; no provision was made for age, occupation and other facts of personal history, or for the duration and severity of illness. One proposed and very desirable heading, "All Other Types of Illness," which would have given a picture of the entire morbidity situation, had to be omitted

SUGGESTIONS FOR REPORTING

In using the form on the reverse side of this card please follow the directions carefully.

Use the card daily, putting a mark for each *new* case. Thus

Disease	Males	Females
Tonsillitis	///	//

And as further new cases are seen, simply add to the check marks, thus

	////	⧸⧸⧸⧸

The value of this record lies in its completeness; it is therefore important to send in the card weekly, even when NO new cases of the specified disease are seen.

Under "Colds" enter bronchitis, coryza, "grippe," laryngitis, pharyngitis and similar conditions.

Under "Children, diseases of" enter all forms that are at present not reportable or shown elsewhere on the card; for instance rickets, pyelitis, malnutrition, etc.

Under "Neuroses" include conditions such as "worry," "indigestion," "neuritis," any condition that is in your opinion based on a functional disturbance of the nervous system.

Under "Surgical" enter operations for any cause, injuries due to accidents, etc.

11-23-26-5000 (21-2953)

SICKNESS REPORT: Week ending.....192....

The number of *NEW CASES* attended by me during the week ending Saturday midnight was as follows:

Disease	Males	Females
Appendicitis		
Arteriosclerosis		
Cancer		
Children, diseases of (outside of reportable and those listed on this card)		
Colds		
Diabetes		
Diarrhea and enteritis (under 2 years)		
Digestive disorders, other		
Gonorrhea		
Gynecological cases:		
a. Operative		
b. Non-operative		
Heart disease		
Neuroses		
Nephritis, acute		
Nephritis, chronic (*Bright's disease*)		
Rheumatism:		
a. Acute rheumatic fever		
b. Chronic arthritis		
Surgical cases, operative, traumatic (except gynecological)		
Syphilis		
Tonsillitis		

(Signed)

.....M.D.

P.O.....

IMPORTANT Please mail report IMMEDIATELY even if NO NEW CASES of above named diseases were attended.

because certain physicians preferred not to disclose the general extent of their practice.

The physicians were asked to report only new cases of the various types of sickness indicated and not new patients, and were furnished stamped and addressed envelopes in which to return the cards to the State Health Department each week.

Results of the study made in New York State were reported by Dr. DePorte in the *Journal of the American Medical Association*, Feb. 16, 1929.

A Continuous Appraisal—George D. Lummis, M.D., Health Officer of Middletown, O., submits a leaf from a book which lies on his desk at all times. It gives a complete statistical record for the year 1928, and by a glance he can answer almost any question which may be directed to him. In this book are also kept the records of all reportable diseases, the laboratory reports on milk, a sheet showing mortality and morbidity for each month, the number of deaths and births, also the five leading diseases, the number of cases reported and deaths therefrom. From this he is practically able to complete his *Ap-*

---

praisal Form, prepare his Annual Report for the City of Middletown, and his Yearly Report to the State Health Department.

Dr. Lummis feels that such a record book would be of great help to health commissioners in cities of 100,000 population or less.

Pasteurized Milk in Massachusetts—The Massachusetts Department of Public Health has recently distributed, through boards of health, physicians and others interested in public health, a statement of the requirements in that state with respect to pasteurization of milk. The state law requires that milk be heated to 140–145° F. for 30 minutes, the object of pasteurization being to destroy the disease germs which are sometimes found in milk. In the last 20 years over 600 milk-borne epidemics have been reported in this country. There is no record of milk-borne epidemic due to properly pasteurized milk.

LABORATORY

C. C. YOUNG

THE CULTIVATION OF ENDAMEBA GINGIVALIS (GROS) FROM THE HUMAN MOUTH *

CHARLES A. KOFOID, PH. D., SC. D., FELLOW A. P. H. A., AND HERBERT G. JOHNSTONE

HOWITT'S (1925) modification of the Locke's egg slant-albumen medium of Boeck and Drbohlav (1924) has proved to be by far the best medium for the growth of amebas from the mouth of man and the monkey. It has been used with great success in routine examination and culture work. Several strains of *Endameba gingivalis* have been cultivated in this laboratory for extended periods, one strain having been maintained for 33 months. With the proper care a strain of ameba may be cultured indefinitely.

The Locke's egg-albumen (L. E. A.) medium consists of coagulated egg slants (containing a small amount of Locke's solution) used as a solid base with the addition of 6 to 10 c.c. of Locke's albumen solution.

1. *Egg slants*—The egg slants are made by cracking 8 washed, fresh eggs into a liter flask containing glass beads; the flask is shaken vigorously until the eggs are homogeneous and 100 c.c. of Locke's solution are added. This mixture is tubed through a sterile apparatus and inspissated in the autoclave for 15 minutes, at 15 lbs. pressure, with all valves closed. The entrapped air is replaced carefully with steam and the slants sterilized for 15 minutes at 15 lbs. pressure. This method produces an evenly coagulated slant without air bubbles.

2. *Locke's solution*—The formula for the Locke's solution used is:

NaCl	9 gm.
$CaCl_2$	0.2 gm.
KCl	0.42 gm.
$NaHCO_3$	0.2 gm.
Glucose	0.251 gm.
Distilled H_2O	1,000 c.c.

The Boeck-Drbohlav formula contained 2.5 gm. of glucose and only 0.4 gm. KCl.

This solution is sterilized in the autoclave at 15 lbs. pressure for 15 minutes. Prolonged sterilization should be avoided as there is a tendency for the glucose to be reduced and a white precipitate of $CaCO_3$ to be formed. If this happens, the fluid should be discarded.

Heretofore the preparation of Locke's solution has consumed much time in the laboratory. The solution was made in 4-liter amounts and, as large quantities were continuously being used, frequent weighings were necessary. The utmost care must be used in the preparation and sterilization as the amebas are very sensitive to any variation in the salt content. The method now followed consists in making separate concentrated solutions of the various ingredients and adding them to sterile distilled water whenever the medium is needed. The following is 40 times the common formula of Locke's solution:

* From the Protozoölogical Section of the California Stomatological Research Group and the Department of Zoölogy of the University of California, under the direction of Professor Charles A. Kofoid, aided by grants from the Carnegie Corporation, the American Dental Association, and the Associated Radiograph Laboratories of San Francisco, Calif.

Salt Solution

Sodium chloride	360 gm.
Calcium chloride	8 gm.
Potassium chloride	16.8 gm.
Water	2,000 c.c.

Sterilize in autoclave for 30 minutes at 15 lbs. pressure.

Sodium Bicarbonate Solution

Sodium bicarbonate	8 gm.
Water	100 c.c.

This solution must be prepared carefully to prevent absorption of carbon dioxide from the air, and it must not be heated or shaken vigorously. The solution is filtered through a fine Berkefeld candle.

Sugar Solution

Dextrose	25.1 gm.
Water	500 c.c.

The sugar solution is sterilized in the Arnold for 20 minutes daily on 3 successive days.

The salt solution is put up in 110 c.c. amounts, the bicarbonate in 5 c.c. amounts and the sugar solution in 10 c.c. amounts. The flasks of salt solution and the tubes of dextrose are capped with paper while the tubes of sodium bicarbonate are corked and covered with paraffine.

To make 2 liters of Locke's solution take a flask of salt solution (110 c.c.), a tube of sodium bicarbonate solution (5 c.c.), a tube of dextrose solution (10 c.c.), and add to 1,885 c.c. of sterile distilled water. The above solutions are made every 3 months and can be kept indefinitely. Two liters of Locke's solution can thus be prepared in about 5 minutes, which is of great advantage when needed in a short time or in cases of emergency.

3. *Locke's albumen-solution*—The white of one egg is carefully cracked into a sterile liter flask containing glass beads, shaken vigorously until frothy; then 500 c.c. of Locke's solution and 20 c.c. of N/20 HCl are added. This quantity of acid proved to be about the right amount to add to a liter of fluid in order to give a pH 7.4–7.6. The remaining 500 c.c. of Locke's solution is added and the whole mixture shaken thoroughly and filtered through a Berkefeld candle. This sterile medium is added aseptically in 6–10 c.c. amounts to the egg slants.

It is possible to make the Locke's egg-albumen medium without filtering, but it has been the experience that the filtered medium gives by far the most satisfactory results. The unfiltered medium is prepared exactly as the filtered with the exception that 2 egg whites instead of one to a liter of Locke's solution are used. The eggs must be sterilized in 90 per cent alcohol before cracking and aseptic precautions observed to avoid contamination. An uninoculated control tube should be run at the time of each transplant.

The medium is warmed to 37° C. previous to inoculation with either fresh or culture material. Subgingival exudate or pus is removed by sterile sharpened applicator sticks or sterile dental scalers, and introduced into the culture tubes. The tubes should be placed immediately in the incubator at 37° C. and at no time should they be subjected to prolonged chilling.

Cultural transplants are made by removing a small amount of the material which collects in the angle formed by the egg slant and the side of the tube with a sterile Pasteur pipette and inoculating this substance into fresh medium warmed to 37° C. Transplants are made every 48 hours.

In addition to Locke's egg-albumen medium several other mediums were tried with the hope of finding one that would (1) permit a growth period of more than 48 hours without transplanting; (2) eliminate some of the harmful types of bacteria and the flagellate *Trichomonas buccalis;* (3) produce rich cultures; and (4) be easily prepared and possess a simple formula.

Locke's-egg slant blood medium reduced the number of bacteria considerably but after the first few transplants

the amebas became scarce. It was found, however, that the cultures could be transplanted every 72 hours instead of the usual 48.

The Ringer-albumen-starch-acriflavine medium used so successfully in the culture of *Endameba dysenteriae* and *Councilmania dissimilis* in this laboratory, proved of no use in the cultivation of *E. gingivalis* of man. As acriflavine is lethal for *E. gingivalis* in dilutions stronger than 1–200,000, the weaker dilutions proved inadequate in eliminating the harmful flagellate and bacteria.

Locke's egg-albumen medium with the addition of rabbit or sheep serum (3 per cent) caused a temporary increase in the number of amebas, but after 6 or 7 transplants the organisms steadily decreased, and although they persisted never again rose to the richness of the first cultures.

The medium consisting of Loeffler's serum slants and Locke's albumen caused the amebas to disappear completely after 48 hours of growth.

Following the suggestions of Koch (1926), the triaminotriphenyl methane dyes, acid fuchsin (National Aniline and Chemical Co.) and ethyl violet (Grübler), were added to L. E. A. in various dilutions to prolong the life and rid the cultures of the harmful bacterial and flagellate forms. It was found, however, that the dilutions suggested as being bactericidal and not amebicidal destroyed the strains of human and monkey amebas in one or two transplants. The ethyl violet in dilutions of 1–50,000 and 1–100,000 proved too severe; the acid fuchsin 1–1,000 did not kill the amebas but reduced the bacteria and *Trichomonas* considerably. It was found that these latter cultures had to be transplanted every 48 hours as usual. A small amount of sterile starch was added to each culture with the hope of prolonging the period between transplants. After 48 hours' incubation some very interesting observations were made. The amebas had increased greatly in size and number while the bacteria and *Trichomonas* had decreased. By the addition of a small amount of starch to the acid fuchsin L. E. A. medium, transplants could be made every 4 days instead of 48 hours. After 4 to 6 transplants the dye was found to be too severe as most of the amebas disappeared. After the second or third transplant in the medium containing the dye, the strains were put in starch L. E. A. without acid fuchsin and the number of amebas greatly increased. It was found that this temporary growth in the presence of acid fuchsin in many cases totally eliminated the flagellates and many of the bacteria.

The most interesting result obtained was that *Endameba gingivalis* was capable of ingesting starch grains. The starch cultures of both human and monkey amebas after 24 or 48 hours' incubation contained many large, sluggish amebas with the endoplasm completely packed with starch grains in various stages of digestion. The pseudopodia were usually few in number and very large. Thirty-two amebas measured in the longest diameter gave an average of 29 μ. This is an increase in size of approximately 50 per cent. A motile ameba was seen to approach a starch grain many times its own size, and after struggling with it for about 10 minutes, it finally moved to a smaller grain which it ingested in an incredibly short time. The formation of a crown of spicule-like pseudopodia was observed on the posterior end of many amebas, to which were attached clumps of small starch grains. Cultures have been maintained for 10 days containing quantities of amebas and *Trichomonas*, both of which were very active and full of starch grains. It is a general rule that cultures of amebas containing *Trichomonas buccalis* soon become foul, and within 48 or 72 hours all of the amebas will have disappeared. With the addition of a small

amount of starch, amebas may be made to tolerate *Trichomonas buccalis* for extended periods. These long period cultures do not always bear transplanting.

With the examination of stained starch culture slides (Schaudinn and iron-hematoxylin) many interesting facts were disclosed. In addition to the abnormal size, many amebas contained within the endoplasm quantities of lightly stained starch grains in various stages of digestion. Some of the grains that had been recently ingested were of the typical angular type while others, partly digested, had been completely rounded in form. It is of interest to note that no vacuoles could be seen surrounding the grains. The pseudopodia were coarsely alveolar and in a few instances clear and non-granular. The endoplasm was distinctly alveolar or coarsely granular and occasionally contained a few cocci and bacilli. After 48 hours' growth many of the amebas became much smaller and rounded. In these forms the ectoplasm was generally lacking, and if present at all, was reduced to a uniform film of 1 or 2 μ in thickness. The liquid contained in the vacuoles was tinged a delicate blue due to the presence of the digested starch. The peculiar type of vacuolation and the heavily staining, granular endoplasm in amebas from starch mediums is in striking contrast to those from either a normal culture or direct smear. The nucleus is the part of the ameba that undergoes the most drastic change. It becomes larger, with an average size of 6 μ, and is generally spherical. The chromatin is completely disarranged and assumes many bizarre formations. Although there are forms in the early cultures that resemble the beaded-central karyosome type of nucleus most of the amebas have nucleuses of extraordinary pattern. The chromatin occurs as huge blobs, coarse granules or irregular aggregates distributed throughout the nucleus. In one ameba 3 nucleuses were found, a fact not hitherto reported. An observation of interest is the peculiar clearness, distribution and number of linin fibers in the nucleuses.

The difficulties encountered in the cultivation of the ameba from the human mouth are not numerous and it is comparatively easy to maintain a strain indefinitely. *Endameba gingivalis* is sensitive to any great change either in the medium or temperature, and it is therefore essential to have carefully prepared mediums and not to subject the cultures to prolonged chilling. The Locke's egg-albumen medium is usually employed in our laboratory for general routine and culture work. The starch medium is used very effectively for the production of rich cultures and the maintenance of stock strains. Starch provides a source of food and the amebas appear to thrive on it. Although many abnormal and rounded forms occur in the starch cultures the normal forms persist in great numbers. Much time is saved as these cultures are transplanted every 4 or 5 days. A judicious use of dyes in combination with either plain L. E. A., or L. E. A. plus starch, rids the cultures of many of the harmful bacteria and flagellates so commonly found in the human mouth.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

National Safety Council Issues Form for Study of Fatal Accidents in the United States—The National Safety Council has prepared a form for use in state bureaus of vital statistics for the description of the more than 90,000 deaths which occur from accidents each year in the United States. At the present time, statistics for fatal accidents in the United States are presented each year only under the titles of the *International List of Causes of Death,* and these give information chiefly on the means of accident.

The new form drafted by the National Safety Council will enable state registrars to secure the following additional facts: the results of the accident, number of dependents left by the deceased, and the class or kind of accident, whether it occurred in the home, in industry, as the result of a vehicular accident, or from other public hazards.

For home accidents, the means of injury are specified, whether the accident was due to a fall, to burns and scalds, asphyxiation, poisoning, or cuts or scratches. For industrial accidents, practically the same information will be gathered for fatalities reported to the state bureaus of vital statistics as are now collected by workmen's compensation commissions.

It is proposed to show the number of industrial accidents involving machinery, vehicles, explosions, electricity, fires and hot substances, poisonous and corrosive substances, falling objects, the handling of objects and the use of hand tools, etc. For vehicular accidents it is purposed to collect facts as to whether the person killed was the pedestrian or driver, whether the accident was the result of a collision, who drove the vehicle, the age and sex of the driver, and other important information needed for accident prevention purposes. For public accidents not involving a vehicle, the statistics will attempt to show whether death resulted from a street or sidewalk accident, in buildings or structures, by drowning, through the use of firearms and through other public accidents not involving a vehicle. On the reverse side of the form a schedule of definitions is given which will guide local and state registrars in the classification of accidents.

When this system goes into full effect in each of the states, it is hoped that the resulting statistics will provide the basis for a broad-gauge accident prevention movement directed at accidents in the home, in industry and on our streets. The form was drafted by a joint committee representing the Statistics Section of the National Safety Council and the Section on Vital Statistics of the American Public Health Association.

The form should be of interest to insurance men, and copies may be obtained from the Statistical Division of the National Safety Council, 108 East Ohio Street, Chicago, Ill.

Tuberculosis in School Children—The Department of Public Health of Massachusetts began in 1924 a 10-year program for the examination of the school children of the state. This study is based on 42,071 children who were given the Von Pirquet tuberculin test during a period of 3 years. The percentage of reactors in the children studied shows a gradual upward trend. Of 902 children aged 5 years, 20.8 per cent

gave a positive test; 30.4 per cent of 5,451 children aged 12 years were positive, and 34.6 per cent of 1,920 children aged 15 years were positive. The study showed no marked variation in the number of reactions in the children of different nationalities when there was no history of contact. But approximately twice the number of children reacted to the tuberculin test when there was a history of exposure to a case of pulmonary tuberculosis. The lowest percentage of contact reactions was present among children of mothers born in England or Scotland. Of 223 exposed children, 38.5 per cent gave positive reactions. Among the non-contacts of the same nationality 22.8 per cent of 1,623 children were positive. In the Latin group, which included children of mothers born in France and Portugal, 55.9 per cent of 259 exposed children were positive, as against 27.5 per cent of 1,123 non-exposed children. The Teutonic group, including children of German and Austrian mothers, showed the highest percentage of reactions among the contacts. Of 75 contacts, 73.3 per cent were positive, as against 24.0 per cent of 533 non-contacts. In some instances there was a much higher incidence of infection among boys than among girls of the same nationality. In the Irish group, 31.8 per cent of the boys gave positive reactions as against 25.7 per cent of the girls; in the Canadian group 35.8 per cent of the boys were positive as against 23.8 per cent of the girls; and in the Teutonic group 38.2 per cent of the boys were positive as against 25.1 per cent of the girls.

Different sections of the same city may show a wide variation in the percentage of reactions. It was found in one city of 60,000 population that the number of children reacting to the tuberculin test in different school districts varied from 11 per cent to 60 per cent. Chronic forms of pulmonary tuberculosis such as are found in granite quarry workers, expose and infect more children than the more acute cases who live a much shorter time after the disease becomes infectious. Crowded living conditions afford more opportunities for contact, and congested areas show a higher percentage of infection.—Henry D. Chadwick and David Zacks, The Incidence of Tuberculous Infection in School Children, *New England J. Med.*, 200: 332–337 (Feb. 14), 1929.

Tonsils and Rheumatism—A survey was made of 439 children who had acute rheumatism. The most susceptible ages for the first attack were between 5 and 15 years. Of the 439 cases, 126 had the first attack between the ages of 5 and 10 years, and 239 had the first attack between the ages of 10 and 15. The first attack appeared in 123 of the 439 children who had their tonsils removed, as compared with 316 where the tonsils were still present. Recurrent attacks of rheumatism occurred less often in children who had their tonsils removed after the first attack than in those whose tonsils were not removed. Of the 316 children who had their first attack before the tonsils were removed, 80 had one or more recurrent attacks of acute rheumatism before enucleation of the tonsils and 56 had their second attack after enucleation of the tonsils. Thirty-one of 123 children who had acute rheumatism for the first time after tonsillectomy had recurrences, and 31 of 159 children who had the tonsils removed after the first attack had recurrences. The incidence of carditis as a complication in acute rheumatism was nearly as frequent in children who had undergone tonsillectomy as in those who had not. Forty per cent of 316 children who did not have their tonsils removed, developed rheumatic endocarditis, as compared with 39 per cent of 123 children who underwent tonsillectomy. Chorea occurred as a complication in acute rheumatism with equal frequency

in children operated and not operated on, but the association of carditis with chorea was less in children whose tonsils had been removed. Tonsils are the avenue of infection in many cases of rheumatism and bear a definite relationship to this disease. Their removal should be advocated in the rheumatic and potentially rheumatic child until more is known of the etiology of the disease.—Albert D. Kaiser, The Relation of the Tonsils to Acute Rheumatism during Childhood, *Am. J. Dis. Child.*, 37: 559–564 (Mar.), 1929.

A Setback in Mid-life Mortality—Since 1920 there have been 5 particularly good health years, and 2 that fell below the general average. For the years 1921, 1922, 1924, 1925 and 1927 the crude death rates for the United States Death Registration States were 11.6, 11.8, 11.8, 11.8 and 11.5 per 1,000 population. For the years 1923 and 1926 the crude death rates were, respectively, 12.3 and 12.2 per 1,000 population. The series of expectations of life at birth for the years 1921, 1922, 1924, 1925 and 1927 runs somewhat irregularly as follows: 58.01, 57.89, 58.11, 58.20, 59.10. The corresponding series of figures for the expectation of life at age 5 was 59.37, 58.97, 58.81, 58.54, and 58.78. At age 37 the continuously decreasing sequence is again shown with a series of 32.86, 32.26, 31.98, 31.50 and 31.47. At birth the expectation of life in 1921 was 58.01 as against 59.10 in 1927. But after the first year of life there is practical equality, namely 61.49 for 1921 and 61.48 for 1927. Thus the gain in expectation of life during the 7-year period from 1921 to 1927, inclusive, is secured chiefly by the improvement in infant mortality. From age 37 on there has been an increase in the mortality rates for 1927 as compared with 1921. At age 42 the death rate was 7.61 per 1,000 in 1921 as compared with 8.37 in 1927. At age 52 the death rate was 12.99 in 1921 as compared with 14.68 in 1927. At age 62 the death rate was 26.78 in 1921 as compared with 29.44 in 1927.

For the industrial policyholders of the Metropolitan Life Insurance Company the matter has a slightly different aspect. As they represent essentially the wage earning population, their expectation of life still falls somewhat short of that for the general population. A gain in expectation of life is recorded up to and including age 5, for 1927 as compared with 1921. As compared with 1922, the year 1927 shows a gain in expectation of life up to age 30. But the mortality conditions have been improving only at the younger ages of life. —*Stat. Bull.*, Met. Life Ins. Co., 10: 1–4 (Feb.), 1929.

Mortality in Childbirth—At the present time the mortality rate in childbirth is lowest in those countries where the delivery of normal cases is almost entirely in the hands of the trained midwife. In England with the midwives in charge of only 50 per cent of the deliveries, the mortality rate is higher than in the countries on the continent where midwives deliver 85 to 90 per cent of the cases. In the United States maternity care has been largely in charge of the medical profession. The number of physicians available for care during childbirth is rapidly diminishing, and there is need for nurses and midwives trained to care for normal patients for whom no physician is available. In the birth registration area of the United States, the maternal mortality rate of 6.5 per 1,000 live births has remained practically the same for the past 20 years. In the southern states of this country inadequate care among the colored women is largely responsible for the high death rate. The average maternal mortality rate in the cities for 1927 was 7.5 per 1,000 live births, as compared with a rate of 5.5 in rural

districts. The death rate from puerperal septicemia was 3.1 per 1,000 live births in the cities, as compared with 1.9 in rural districts. The lower death rate for rural districts may be due to less interference with labor, and a reduction of infection associated with operative deliveries. Puerperal septicemia is the cause of over 40 per cent of maternal deaths, and eclampsia the cause of more than 25 per cent. Almost 20 per cent of deaths are due to accidents of pregnancy and labor which could be greatly reduced by proper supervision.

About 40 per cent of the births in this country are in the hands of midwives, and over 90 per cent of these women are untrained. During the past 10 years the New York State Department of Health has been active in improving the practice of the midwife, and as a result the number of midwives has been greatly reduced. In 1916 midwives reported 16.13 per cent of the total births, as against 7.09 per cent in 1926. In 1911 a school for midwives was established in connection with the maternity service at Bellevue Hospital. The midwives at the school have delivered 13,762 women since 1911. One hundred and thirty-three of the cases were transferred to Bellevue for hospital care. There were 11 maternal deaths, and 4 of these occurred among the cases transferred to the hospital. The maternal death rate was 0.75 per 1,000 live births; the stillbirth rate was 1.77 per cent; and operative delivery by forceps was 2.32 per cent.

As a result of state registration of midwives and on account of restricted immigration, the need and demand for midwives will rapidly decrease except possibly among the rural colored population of the South. Prenatal care would increase the number of normal deliveries and lessen the number of operative deliveries. Furthermore, the standard of maternity care would be greatly improved if the number of properly organized maternity hospitals could be increased, and if maternity services were established in local general hospitals for the care of abnormal obstetrical cases.—Frederick W. Rice, The Problem of Reducing Mortality Associated with Childbirth, *New York State J. Med.*, 29: 262–267 (Mar. 1), 1929.

Suicides in Budapest—A comparison of figures relating to the rate of suicides in Budapest shows that the rate was lower in prewar years than it has been in postwar years. The number of suicides was 334 per 1,000,000 inhabitants in 1874; 462 in 1910–1913; 357 in 1914–1918; and 505 in 1923–1927. Prior to the war 68 per cent of the suicides were men, and 32 per cent were women. For the period 1923 to 1927, 57 per cent were men and 43 per cent were women. The numerical increase of suicides was in young women and in old people of both sexes. From the point of view of religions, the number of suicides is lowest among the Roman Catholics, next among the Jews, and highest among the Protestants. From the standpoint of occupation, suicides are most prevalent among those having an uncertain existence, among merchants, those dealing with credit business, and craftsmen's assistants. Among women, domestic servants and pensioned widows are to the fore. High suicide indexes such as exist in Budapest are found also in Berlin and Dresden.—Suicides in Budapest and in the Large European Centers, *J. A. M. A.*, 92: 999 (Mar. 23), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Drinking Fountains—The drinking fountain has not received as much attention from public health officials as its widespread use warrants. Several years ago the Minnesota Department of Health studied this subject and published its findings in *Public Health Reports* for May 11, 1917. More recently, that department has deemed it of value again to draw to the notice of the public the fact that not all types of drinking fountains are satisfactory. This was done through the adoption of the resolution given below:

WHEREAS, public drinking fountains have largely replaced the common drinking cup and are provided in a great many places accessible to the public, and

WHEREAS, investigations have shown that disease producing bacteria may be transmitted from one person to another through the use of improperly constructed or improperly operated drinking fountains, and

WHEREAS, the observations made by the State Board of Health have revealed the presence of insanitary types of drinking fountains in many public and semi-public places throughout the state, therefore be it

RESOLVED that the attention of the public be drawn to the fact that not all drinking fountains are satisfactory and that to be sanitary, drinking fountains should conform with the following general requirements:

1. The jet of water emerging from the fountain should be slanting so that discharged water does not fall back onto the surface.

2. The orifices from which the water emerges should be protected in such manner that they cannot be touched by the lips or be contaminated by droppings from the mouth or by splashings from the base beneath the orifices, and

3. An adequate supply of pure water, under sufficient pressure, properly controlled, should be provided in order to insure satisfactory operation of the fountain.

Significance of Bacteria of the Coli-Aerogenes Group in Drinking Water; Two Possible Sources—American biologists have found that organisms of the coli-aerogenes group are divisible into two subgroups by their reactions to four tests, and have suggested that the coli subgroup is derived mainly from animal intestines, while the aerogenes subgroup occurs commonly in soil and water. The distinguishing tests are: (1) the high ratio of carbon dioxide to hydrogen in the gas evolved from cultures of the aerogenes subgroup in dextrose broth (Clark). Methyl red is consequently colored red by growth of coli subgroup, yellow by aerogenes. (2) The formation of a red color when 5 c.c. of 10 per cent caustic potash is added to a 4-days Clark culture of aerogenes subgroup and incubated for a further 24 hours. Coli subgroup does not give this color (Voges-Proskauer reaction). (3) and (4) The growth of aerogenes subgroup in liquid mediums containing uric acid (Koser) and sodium citrate (Koser-Simmons) respectively. In both cases the coli subgroup is inhibited. The authors carried out comparative tests on 510 cultures isolated from natural waters, and 490 cultures obtained directly from human and animal excrement. The standard German method for testing gas production (Eijkmann-Bulir at 46° C.) was followed. The water cultures gave 95 per cent gas formers, the fecal 94.5 per cent. Applying the American tests, the proportions were 96.2 per cent and 95.9 per cent. By both methods the presence of *B. aerogenes* was shown in 1.4 per cent of the water cultures, and in 0.4 per cent

of the others. The American distinguishing tests for coli and aerogenes are superfluous when the Bulir gas forming test is carried out at 46° C. and this gives strong evidence of intestinal origin of a strain of coli.—Minkewitsch, Trofimuk, Wedenjapin at the Acad. Mil. Med. Leningrad, *Ztschr. f. Hyg. u. Infectionskrankh.*, 109: 348, 1928. (From papers of Water Pollution Research Board, England.)

Biological Purification of Town Sewage in Sewage Fish Ponds—A description is given of the sewage fish ponds of the "Mittlere Isar A.—G" in Munich which are almost completed. Their function is to purify biologically the sewage from Munich, which has already been mechanically clarified. The ponds cover 233 hectares, and consist of 30 large ponds for breeding carp, and other smaller ponds for hatching. The total production, exclusive of tench, which also breed, is about 100,000 kg. of carp, and the gross yield per hectare of tank-surface is estimated at 1,000 R. M.—A. Schillinger, Paper read before Meeting of Verein deutscher Chemiker, *Chem. Ztg.*, 52: 481, 1928. (From papers of Water Pollution Research Board, England.)

Size of Pores and the Mechanism of the Berkefeld Filter—A description is given of some experiments to discover whether the mechanism of the Berkefeld filter depends solely on straining or is partly due to the adsorption force exerted on the bacteria by the diatomaceous earth. The method was to determine the maximum and average size of the pores and compare the result with the size of bacteria. The existence of some adsorption mechanism would be proved if the pores were the larger. The size of the largest pores was ascertained by measuring the pressure necessary to drive air bubbles through a cylinder filled with water, and calculating the value from Einstein's formula. The average size of the pores was found by noting the quantity of water passing through the cylinder in unit time at unit pressure, and calculating the value from Bechhold's formula. The majority of Berkefeld filters in use were found to have an average pore size of about 2 μ, which would only retain bacteria to the size of 1 μ, showing that their efficacy is due to an adsorption mechanism. Owing to this, it is possible to choose comparatively big pores for these filters, without making them permeable to germs, and thus give them a high productivity.—H. Hock, *Chem. Fabrik.*, 645, 1928. (From papers of Water Pollution Research Board, England.)

Causes and Prevention of Hydrogen Sulphide in Abattoir Sewage—Details are given of an investigation at Sydney arising from hydrogen sulphide formation, with consequent corrosion, in concrete sewers carrying abattoir effluents. The installation of a plant to recover part of the suspended solids failed to eliminate the trouble. The time of decomposition, as measured by the discoloration of lead acetate paper, of mixtures of ½ per cent of blood in salt solution with varying quantities of dissolved and suspended proteins, was found to be 4 to 10 days, as against 1½ hours in the sewers. It was suggested that putrefying paunch contents, delayed in passing from the by-products works to the sewers, inoculated the fresh material—a view supported by the fact that at laboratory temperatures the time of decomposition was in one instance 24 hours, against 1 hour at 37° C. Cultures from paunch were made on agar containing ferrous sulphate, and dark-stained colonies indicated the presence of an organism producing hydrogen sulphide, subsequently identified as *B. coli communis*, which was found to be associated with the coarser solids in paunch. Abattoir discharges during the night were of such

a temperature as to provide optimum conditions for bacterial growth; a cooling system was therefore introduced, and hydrogen sulphide fixed by treatment with iron, with sufficient lime to inhibit multiplication of organisms. The authors conclude that the desiderata for gas elimination are: maximum removal of solids; avoidance of delay in discharge to sewers; cooling of effluents, and sterilization of plant when shut down.—A. B. Porter and J. A. Cresswick, *J. Soc. Chem. Ind.*, 47: 380T, 1928. (From papers of Water Pollution Research Board, England.)

General Review of the Studies of Plankton of Large Rivers—In this article are collected the results obtained by numerous workers from studies of plankton in rivers in France, Great Britain, Germany, Austro-Hungary, Italy, Spain, Switzerland, Sweden, Russia, Asia, Africa and America. The author correlates this information in the second part of the article which deals with the characteristics of plankton in rapid flowing rivers. A comparison is also given of the phytoplankton of the Loire and of rapid flowing rivers.—J. des Cilleuls, *Internat. Rev. d. ges. Hydrobiol. u. Hydrograph.*, 20: 174, 1928. (From papers of Water Pollution Research Board, England.)

Interesting Features of Audubon Park Natatorium, New Orleans, La.—Twin pools from 3′ to 9′ in depth, a separate pool 40′ x 80′ for children, an ornamental concourse around the pools, a dry moat and fence outside the concourse, pressure filters, chlorine dosing apparatus, pumps, lighting system, two bath houses each 30′ x 214′, roadways and parking place for 600 cars, comprise this natatorium which was constructed at a cost of $250,000, of which $90,000 was the cost of the pools.

Automatic safety valves permit ground water to enter the pools when they are nearly empty, thus relieving the pressure on the underside of the floor. Twin pools permit the cleaning of one pool while the other is in service. The usual dangerous pipe ladder is replaced by notches forming steps in the concrete wall, and a hand rail which does not reach to the water. The filter capacity is 100,000 gallons an hour. Alum is used as a flocculent. Bath houses are provided with lockers, dressing rooms, private showers, and a passage 35′ long provided with a barrage of showers and 6 inches of flowing water for cleansing the feet for a pool entrance. Careful inspection of bathers and water inspections are made.—William Scheppegrell, *Am. City*, 39, 4: 129–130 (Oct.), 1928. Abstr. S. H. Smith.

Pollution of Tidal and Non-tidal Waters—The author gives a general review of the causes and effects of pollution in tidal and non-tidal waters. The general effect of all pollution is to degrade or to destroy normal life in the affected stream. It may supplant or supplement normal flora and fauna by other organisms and may render the stream incapable of supporting fish life. In this connection reference is made to the work of Butcher and Pentelow on the River Lark.

With regard to the effects of pollution on the dissolved oxygen content of streams, the author quotes Adeney's work on the aeration of water and gives limiting rates for the absorption of air by water at different temperatures. In non-tidal streams the effects of pollution only manifest themselves below the point of discharge, but in tidal waters the reversal of flow produced by the tide causes pollution to travel both above and below the point of entry and retards the escape of effluents from the river. On the other hand, it tends to stir up matter which otherwise would accumulate on the bottom and ferment,

giving rise to a nuisance. The main effect of pollution on fish life is the reduction of the dissolved oxygen in the water.

A study of the oxygen requirements of fish has shown that the dissolved oxygen in the water of salmon and trout streams should not be allowed to fall below 70 per cent saturation or below 50 per cent for other fish. The author concludes with a discussion of the law with regard to river pollution and gives his views as to the duties which should be carried out by river authorities responsible for the diminution of pollution.—J. H. Coste, *Tr. Soc. Chem. Ind.*, 47: 133, 1928. (From papers of Water Pollution Research Board, England.)

Production of Milk of Low Bacterial Content by Means of Milking Machines—An Alfa-Laval milking machine, typical of most modern machines, was used with two milking units. One unit was washed, brushed, and rinsed in water at 185° F. after each milking; in the other all rubber parts were washed, brushed and sterilized by steam for 10 minutes at 210° F. after each milking. Disinfectants were not considered because "as used in practice they are not to be compared in efficiency with less expensive sterilization by steam."

Plate counts showed enormous fluctuations with both units. After other possibilities were eliminated, the contamination was found, by means of a suspension of carmine, to be due to small quantities of water in the vacuum pipe line finding their way into the receiving pails. By turning all vacuum supply taps upward, giving a generous slope to each section of the vacuum pipe line, and providing drain cocks at each low point, leakage was eliminated, and excellent results followed. Of 191 samples of 28-hour old milk examined for each unit over a period of 1 year, the sterile unit showed 173 below 10,000 per c.c. and 190 below 200,000 per c.c.; while for the washed unit 151 were below 10,000 per c.c., 167 were below 200,000 per c.c., and 20 were over 500,000 per c.c. The average keeping quality of milk at 60° F. was 96 hours for the sterile unit and 86 hours for the washed unit. In machines from which test cup liners are readily removed, steam sterilization is successful, without seriously shortening the life of rubber parts.—A. T. R. Mattick and F. Procter, *J. Hyg.*, 27, 2: 215–224 (Jan.), 1928. Abstr. A. W. Fuchs.

Bacterial Examination of Water in Public Swimming Baths—The author reviews the literature of transmission of disease by swimming baths and of bacterial standards. Practically all of the standards considered are of United States origin.

Experimental results obtained from a number of places in England during 1925–26 are given. These data include bacterial results, methods of operating the bathing pools, number of persons using baths and effects of temperature.

The author concludes in part that: (1) Pollution is less in cold weather than in warm, regardless of methods; (2) continuous filtration is superior to occasional emptying and filling with fresh water; (3) standard adopted should be as stringent as that for drinking water (U. S. Treasury), and (4) it is not possible to maintain this standard without continuous disinfection with some agent such as chlorine.—G. K. Bowes, *J. State Med.*, 36, 9: 521–545 (Sept.), 1928. Abstr. C. T. Butterfield.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Relation of Illumination to Ocular Efficiency and Ocular Fatigue—The office of Industrial Hygiene of the U. S. Public Health Service announces the publication shortly of *Public Health Bulletin No. 181,* which is devoted to a study of the relationship of illumination to ocular efficiency and fatigue.

This study was made during the period 1924 to 1926, in the main post office of Chicago. The purposes of the study were to determine the degree of illumination under which the distribution of mail might be made with the greatest ease and efficiency; to demonstrate ocular fatigue and determine its relation to different degrees of illumination.

In order to rule out the effects of the mental attitude of the worker and the effects of variations in the amount of work on hand, the sorting of small letter mail by the night shift received much attention. In this case, it was found that there resulted an increase of approximately 8 per cent in sorting speed when the illumination was increased from 2.7 to 10.7 foot candles.

In a series of tests, where 1,000 specially prepared cards were used as the test mail, it was found that the time to read the addresses on the cards decreased 8 per cent when the intensity of illumination was increased from 2.5 to 10 foot candles.

The studies of the effect of the degree of illumination upon ocular fatigue showed that visual acuity improved after the subjects had worked under high illumination for a sufficient length of time, and decreased correspondingly after working under low intensities of illumination. This is, unquestionably, a very important significant finding.

Studies on refractive errors indicate the incidence of these defects to be rather high. Fifty per cent of the clerks wore glasses.—*Pub. Health Rep.,* 44, 8 (Feb. 22), 1929. L. G.

French Experience Regarding Occupational Diseases Caused by X-rays and Radio-Active Substances—The first signs of exposure to these radiations consist in blood changes, wherein: first, the numbers of white blood corpuscles and then the red blood corpuscles are altered. The first of the white blood changes consists in a reduction of the leucocytes. Later, this is followed by a decrease in the number of red blood corpuscles, at which time these are characterized by inequality of size and shape. There is also a lowering of arterial pressure, but, nevertheless, no disturbance of the cardiovascular equilibrium. There may be changes in the reproductive organs, producing sterility and disordered menstruation. Finally, there may be disturbances of nutrition, characterized by loss of weight and other subjective symptoms. Locally, there may be traumatic effects resulting in radio-dermatitis, burns and lesions of the skin and underlying tissues.

The protective measures, recommended by the French Academy of Medicine, consist in adequate ventilation of work places, the use of rubber gloves and of forceps for handling of the materials, protection from the rays by plates of metallic lead and periodic medical and blood examination of the workers. The radioactive substances considered as injurious include the following: radium, radium emanation, radioactivity induced by radium or radon,

polonium, actinium, thorium, mesothorium, and radiothorium, thorium X, emanation of thorium, or thoron, and radioactivity induced by uranium, and its salts, uranium X, and ionium.

The following types of industrial processes were considered potential sources of poisoning from these substances: Plants for the extraction of radioactive elements from minerals, manufacture of derivative radioactive substances; plants making medical appliances for radium therapy, or X-ray appliances; laboratories for research or measurement of radioactive substances and X-rays; plants making radioactive chemical or pharmaceutical products, and factories making radioactive luminous products or workshops in which these paints are applied; clinics and sanatoriums, centers for the treatment of cancer; enterprises for the sale of radium and radioactive substances; and manufacturing establishments using X-rays.—Abstr., *Month. Labor Rev.*, 28, 1: 77 (Jan.), 1929. L. G.

Road Tar Poisoning—This contribution presents the report of the case of a workman, aged 30, employed as a tar wagon tender, engaged in highway construction.

In the usual fashion, the tar was melted in a roadside oven, but was allowed to flow from the tank by some passing school children. The worker in question waded through a considerable body of tar and finally succeeded in closing the spigot.

Later, during the same day, the worker was carried to a hospital, shortly after becoming violently ill and experiencing convulsive seizures. It was found that marked pulmonary edema was present, as were also superficial burns of the mouth and upper respiratory tract. After one week in the hospital he was discharged, but shortly after developed a severe hemorrhage from the respiratory tract. From this time on, he presented a condition of multiple hemorrhage, nephritis, anemia and general emaciation, followed later by neurasthenic and hysterical symptoms.

The symptomatology associated with the nervous system continually increased and, finally, resulted in an abnormal mental state, as well as paralysis of the right leg.

Coal tar is the residue after coal tar distillation is complete. It consists of a number of complex organic materials among which are phenols and naphthalene.—*J. A. M. A.*, 92, 9: 695 (Mar. 2), 1929. L. G.

Compensation for Silicosis—The British Home Office has now abruptly abandoned its plan of extending compensation for silica to one industry at a time and has instead issued a comprehensive draft scheme for granting compensation for death and total disability in practically every occupation in which a silica risk is present.

It is important to note that under this new plan workers in the initial stages of the disease are not entitled to compensation. Compensation should be awarded only for total disability or death, but it is the plan to study each industry for the purpose of linking up preventive procedure with compensation award.

To the abstractor, this appears to be a most rational and commendable step in the study and mitigation of occupational diseases. It would be well if we, in the United States, would follow such procedures.—*Month. Labor Rev.*, 28, 1 (Jan.), 1929. L. G.

Pneumonokoniosis from Sand Blasting—This paper presents a detailed examination of 26 men employed in the process of sand blasting. In 16 cases pronounced X-ray findings were found. In 2 of these tuberculosis and pneumonokoniosis were found, in 2 tuberculosis without pneumonokoniosis, and in 10 silicosis was found, 7 of which

presented changes of very marked extent.

The duration of exposure in all cases was relatively short: in 1, 8 years; in 1, 6 years; in 2, 4 years; in 1, 3 years; and in the remainder less than 3 years. Of the workers the older ones presented more marked evidence of injury.

Physical signs were comparatively slight in spite of the fact that in many cases the X-rays showed advanced disease. Chest expansion was apparently a good index, being poor in most cases.

Four of the 26 workers died shortly, and 4 others who were examined at a later period showed marked extension of the pathological process.—E. V. Müller, *Zentralb. f. Gewerbhyg.*, 5: 148 (May), 1928; Abst., *J. Indust. Hyg.*, Feb., 1929, p. 36. L. G.

The Etiology of Silicosis—There are five milestones to our present attitude toward this disease: (1) Agricola in the 16th century pointed out that there were two kinds of injurious dust, one non-corrosive and the other corrosive; (2) Alison, in the early part of the 19th century, established the association between dust-phthisis and tuberculosis (or tubercles); (3) Zenker, in 1867, showed that lung pigmentation was directly due to inhaled particles; (4) Collis, in 1915, insisted upon the importance of free silica, SiO_2, and that in industry no other dust was of importance in dust-phthisis; and (5) McCrae, just before Collis's lecture, announced that the particles of free silica found in the lungs were under 9 microns in diameter as a rule; and about the same time Watkins-Pitchford noted the same.

Two types of silicosis are now recognized, one uncomplicated, and the other complicated, by an infective process of which the most common is tuberculosis. The tissue cells concerned in both processes belong to the same cell system, i.e., the "lymphatic cell" of Calmette. Gye and Kettle, and the writer, have advanced the view that the behavior of silica dust is related to its slow solubility in the tissues, citing 7 facts to support this. The minute size of the particles, the resulting phagocytosis, the concentration of dust, duration and conditions of exposure are the factors determining dust-phthisis while pigmentation is not characteristic of free silica, but is due to carbon inhaled as smoke or dust.

So-called "miners' phthisis" means superimposed infection on the fibrosis already set up and favors acute pneumococcal or streptococcal infections as well as tuberculosis. Guinea pig experiments show that silica dust remains in the lungs up to the time of death, but coal dust will have practically disappeared in an equal time. (Discussion of the forms of clinical silicosis follows under the headings of silicosis, tuberculo-silicosis, and silico-tuberculosis.)

Experiments show that it is difficult to infect animals with dry tubercle bacilli, even when associated with dust, but it is easy to produce inhalation infection with microörganisms suspended in droplets of water. "Two hours' summer sun may kill a culture of *B. tuberculosis*. The bacilli may, however, survive up to 10 days in dry dust exposed to a poor light. They may remain virulent for months in wet mud or garden soil." Hence, conditions in mines favor the viability of the tubercle bacillus, as it has been noted that water particles may occur in the proportion of 150 to every dust particle.

Furthermore, Calmette points out that water particles from 2 to 15 microns in diameter are respirable and may remain in suspension in the air up to 7 hours. Therefore droplet infection is possible and the ideal conditions for the same obtain at least in the Witwatersrand mines.

Light and dryness are the enemies of the tubercle bacillus—conditions which do not exist in these mines. Silico-tuberculosis is only met with in those

dusty trades that use water for dust laying. Coal miners (colliers) work in dry surroundings and therefore have no silico-tuberculosis. While the inhalation route may be the common path of tuberculous infection in dusty trades, the use of water for dust prevention is not an unmixed blessing, for while it hinders the dust factor it facilitates the tuberculosis factor. Furthermore, droplets facilitate the entry of dust particles. This may explain the comparatively disappointing results by the use of water in mines to reduce air-borne dust. It is, however, at present the only available method for dust laying in many trades and its use has been followed by a decrease in pneumonokoniosis.

The use of ventilation in coal mines has eradicated pneumonokoniosis, not the use of water. Hence, a phthisis-producing industry depends not only upon the inhalation of dust but upon conditions which favor inhalation infections and super-infections with the tubercle bacillus.

"Tuberculosis is an environmental disease rather than an infectious disease in the ordinary sense." Conditions in some industries favor "case to case infection and super-infection and the inhalation route is suggested as a common route (dust-phthisis is proverbially non-infectious in the home)." Infection may be unimportant in ordinary tuberculosis, but it does not follow that it is an unimportant factor in silico-tuberculosis. "Dr. Louis Irvine, Chairman of the Miners' Phthisis Medical Bureau, has been watching our silicosis for 25 years, and he tells me that the variety he now sees is becoming more and more like ordinary chronic fibroid phthisis. Professor E.-L. Collis gives me similar information based on his experience with the disease in Great Britain." It is probable that certain metallic dusts may modify the disease, judging from the studies of hemochromatosis, and while silicosis is predominantly nodular in distribution, it is likely that the drier the working conditions, and the less soot present, the greater the part played by the interstitial process.

Experts will, at the first glance, recognize the disease, at the second, the industry, and at the third, the district. Engineers are always asking how much dust it takes to produce miners' phthisis and how much is inhaled in a unit of time; but it is difficult to explain that individuals vary in their ability to deal with dust, so that the dust sampling apparatus will not tell how much dust is retained nor its endangering effects. As Haldane points out, "Man is not a machine" (nineteen pages of discussion follow).—J. Mavrogordato, *Rapports*, IV^e Reunion de la Commission Internationale Permanente pour l'Etude des Maladies Professionnelles, Lyon, 3–6: 1–23 (Avril), 1929, Société Anonyme de l'Imprimerie A. Rey, 4 Rue Gentil, 4.

Report of South African Institute for Medical Research—This report discloses some interesting experimental work conducted with asbestos dust. Apparently the pathological changes produced in animals were similar to those produced in workers, the time element, however, being longer. Amorphous silica dust apparently produced a fibrosis out of proportion to the quantity of dust present, suggesting that this is perhaps more readily soluble than certain other forms of silica.

Routine studies on tuberculin reactions of individual mine workers have been conducted. So far, however, only one death from tuberculosis has occurred among those who gave a positive tuberculin reaction.—*Annual Report of the South African Institute for Medical Research for the year ended 31st December, 1927*, Dept. Indust. Hyg., pp. 28–31, Johannesburg, 1928. Abstr. *J. Indust. Hyg.*, Feb., 1929, p. 40. L. G.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Nutritive Value of Milk. I. The Production of Nutritional Anemia in Albino Rats through Exclusive Whole Milk Diets—As a step in the study of food value of milk, rats were fed exclusively whole milk diets. Milk from three groups of Holstein cows on very different rations was fed to three groups of rats. With two exceptions all rats grew well for 3 weeks; growth then slowed, and stopped after 6 weeks. Rats then maintained their weight for several weeks, after which there was decline and death. Anemia was present and was confirmed by post-mortem examination. Another group of rats was fed mixed milk from an entire herd of Holsteins and Jerseys, with the same results. Hemoglobin determinations on rats on an exclusive milk diet for 11 weeks showed between 2 and 3 gm. of hemoglobin per 100 c.c. compared with 15 to 16.5 gm. per 100 c.c. for normal rats. In attempting to eliminate the dietary anemia by supplementary feeding, a number of procedures were studied, to be presented in a subsequent paper. The only success in correcting the anemia was by the use of specially prepared yeast, hog liver, or solutions of iron and copper fed simultaneously. The procedure is described for determining the preventive or curative power of the test substances by means of hemoglobin determinations on the blood of the test animals.—W. E. Krauss, *J. Dairy Sci.*, 12: 74 (Jan.), 1929.

Nutritional Value of Copper in Powdered Whole Milk—Young rats, 25 to 27 days old, were fed whole milk powder supplemented with cod liver oil. Weight and hemoglobin determinations were made weekly. Growth curves and hemoglobin determinations are shown for animals receiving whole milk and those receiving whole milk plus iron. Those on the whole milk diet failed to grow and were anemic, while those on the iron supplement showed good growth and hemoglobin production for a period of 10 weeks. The powdered milk contained about 0.0006 per cent copper due to the solvent action of the milk on the copper evaporating pan. It is contended that the presence of minimal amounts of copper may be beneficial instead of detrimental in spite of what has been written on the deleterious effect of copper in milk and the steps taken by manufacturers to eliminate traces of this metal. Work of other investigators is cited to show the favorable effect of small amounts of copper in nutrition.—R. W. Titus and J. S. Hughes, *J. Dairy Sci.*, 12: 90 (Jan.), 1929.

Relative Food Values of Brown (from "Entire" Wheat Grain) and White (from Endosperm of Grain) Wheaten Flour, and Their Comparative Potency for the Prevention of Xerophthalmia in Guinea Pigs—A slight superiority of whole wheat flour over patent flour in its content of vitamin A has been shown in a series of feeding experiments conducted on guinea pigs. In the general discussion of the relative value of brown (whole wheat) and white (patent) flour, it is emphasized that both flours are deficient in a number of essential nutritive factors, but that these deficiencies are not significant when the diet is liberal and varied. The difference in content of vitamin A is thought to be of signifi-

cance only when the diet is extremely restricted, as when it consists largely of bread supplemented by margarine, jam, and perhaps fruits. Under these conditions whole wheat flour should be recommended in place of white flour.—(E. J. Sheehy, *Roy. Irish Acad. Proc.*, 37 (1927), Sec. B, No. 27, pp. 415–425)—Abstract, *Exper. Sta. Rec.*, 60: 394 (Mar.), 1929.

Association of Vitamin A with Greenness in Plant Tissue. II. The Vitamin A Content of Asparagus—Previous experiments (Abstract, *A. J. P. H.*, Nov., 1927) on the vitamin A content of head and leaf lettuce suggested the possible variation in this vitamin in green and bleached asparagus tips. Bleached tips were secured by covering rows with soil and cutting the stalks before emergence from the surface. Fresh, cooked, and canned asparagus, both green and bleached, were fed to albino rats which had been depleted in vitamin A by preliminary diet, and growth determinations were ascertained over a period of 8 weeks. Chemical analyses of the asparagus, and growth curves on the various diets, are given.

Fresh asparagus in daily amounts of 0.1 gm. was fed throughout one experiment, and the fresh bleached asparagus was fed in the same amount except in one experiment where it was increased to 0.5 gm. The result was an average gain of 20 gm. and no deaths on the fresh green asparagus, while on the bleached, health and weight declined and all animals were dead at the end of the 5th week, whether on 0.5 gm. or 0.1 gm. The daily ration of cooked asparagus was 0.1 gm., both for the green and white products. Animals fared better on the cooked product and there was not such a difference between the green and the bleached, but animals on the latter fared better than on the fresh bleached. Canned asparagus, blanched 3 minutes, packed in cans, sealed and processed for 25 minutes (at 10 lb. pressure), was fed in 0.1 gm. daily doses for the green, and 0.2 gm. daily for the bleached. Animals on canned green asparagus recovered and made good growth, but those on the canned bleached asparagus declined and died at a rapid rate after the 2d week.

The authors point to the possible correlation between the depth of chlorophyl and the vitamin A content, although there is no evidence that the two are identical. It is also concluded that the inadequacy of bleached asparagus as food may not be due alone to vitamin A deficiency, but to deleterious chemical compounds, since cooking in an open kettle improved its nutritive value to some extent. Chemical analyses showed that the green tissue was lower in water and iron than the bleached, but higher in ash, nitrogen, sulfur, calcium, and phosphorus.—John W. Crist and Marie Dye, *J. Biol. Chem.*, 81: 525 (Mar.), 1929.

Vitamin A, B, and C Content of Artificially versus Naturally Ripened Tomatoes—The increased commercial use of ethylene in the ripening of fruits and vegetables prompted this investigation to determine the effect on the vitamin content of tomatoes. Tomatoes grown under inspection were picked when the " green mature " stage was reached. These were divided into 3 lots, one fed as picked green from the vines, the second ripened at room temperature, the third treated with an ethylene-air mixture. A fourth lot consisted of tomatoes ripened on the vines. The ethylene-air mixture, approximately 1: 800, was passed over the tomatoes in a bell jar provided with inlet and outlet tubes.

Rats, 40 to 50 gm. weight, were used for testing vitamins A and B, and guinea pigs, 6 to 8 weeks old, for vitamin C. In testing for vitamin B (the complex) the basal diet, casein, starch, butterfat, lard, salt mixture, was supplemented

with cod liver oil. Four gm. daily, for a period of 8 weeks, of green tomatoes, air ripened tomatoes, ethylene-air ripened, and vine ripened tomatoes were fed respectively to four groups of rats, the average daily consumption being practically the same for all groups. Growth curves show no great differences for any of these groups and the uniform gain in weight seems to warrant the conclusion that the amount of vitamin B complex did not differ in green tomatoes and those ripened artificially or naturally. The basal diet used for determining vitamin A content was irradiated to insure a supply of vitamin D.

At the end of the vitamin A depletion period, animals, at an average weight of 122 gm., were divided into 4 groups and fed as in the test for vitamin B, the amount being 2 gm. of tomatoes per animal per day. Positive controls were given 10 drops of cod liver oil daily. Here the growth curves indicate no material difference between the groups, although rats on the green tomatoes gained materially less weight than the others. The data here indicate the same amount of vitamin A in ripened tomatoes, whether by natural or artificial means, and an amount somewhat less in green tomatoes. Guinea pigs, after a preliminary diet to insure adequacy of vitamin C, were divided into negative and positive controls, the latter being given 3 c.c. of canned tomato juice daily. Four groups were fed daily 4 gm. of the 4 lots of tomatoes. Animals were weighed twice a week and autopsies performed at the end of the experiment. Positive controls showed no scurvy and negative controls severe scurvy. Guinea pigs on green tomatoes showed definite symptoms of scurvy; incipient scurvy appeared in some of the animals on the ripened, and air ripened, tomatoes but there was no difference between the two groups, both being superior in health to the group on green tomatoes. Guinea pigs on the vine ripened tomatoes were in the healthiest and best condition with no indication of scurvy. The authors conclude that tomatoes ripened by ethylene are equivalent to tomatoes ripened in the air so far as the vitamins A, B, and C are concerned.—Margaret C. House, P. Mabel Nelson, and E. S. Haber, *J. Biol. Chem.*, 81: 495 (Mar.), 1929.

Antirachitic Factor in Burbot Liver Oil—The burbot fish, sometimes called "lawyer fish" or "eel pout," is the nearest fresh-water relative of the cod, but is used for fertilizer and seldom for human food. The average fish weighs 3 lb. while the liver is alleged to be 6 times as large as that of any other fish of inland waters. One liver used in the experiment weighed 0.55 lb. The percentage of oil secured varied from 36 to 56. Because of the announcement by previous investigators that the liver of this fish probably contained antirachitic vitamins, this study was undertaken. Fresh livers were cooked under pressure and the oil which rose to the surface was skimmed and used in this experiment. Rats on a ricketogenic diet for 21 to 23 days were given for 10 additional days the diet supplemented with the burbot liver oil or cod liver oil, after which they were chloroformed and the antirachitic action measured by the "line test" technic. Varying percentages of the supplementary oil were added, from 2 to as low as 0.007. A table of results shows that 2 per cent cod liver oil ration was required for complete healing as against 0.125 per cent burbot liver oil. The 0.5 per cent cod liver oil and 0.06 burbot liver oil gave comparable results. With 0.03 per cent cod liver oil there was no healing in 3 cases and slight in 2 cases, but the same percentage of burbot liver oil showed good signs of healing. Two rats on the 0.007 per cent burbot liver oil were comparable to those on 0.06 per cent cod liver oil. Results indicate a potency in burbot liver oil about 8 times

that of cod liver oil, although there is doubt if this is due to inherent properties of the oil or variations in the individual samples, in view of recent work in which the potency of cod liver is shown to be in inverse ratio to its oil content. (*Proc. Soc. Exper. Biol. & Med.*, 25, 653 (May), 1928).—Bertha Clow and Abby Marlatt, *Indust. & Eng. Chem.*, 21: 281 (Mar.), 1929.

Effects of Massive Doses of Irradiated Ergosterol—Several investigators have shown the effect of small doses of irradiated ergosterol, but the study of large doses of vitamin D has been impossible because of impurity until the development of the irradiated ergosterol. Rats averaging 50 to 70 gm. were fed the low phosphorus rickets-genic diet for 4 weeks and rickets was confirmed by autopsy. The animals were put in 3 groups, one exposed to reflected daylight, the second given in addition 2 per cent cod liver oil, and the third, a solution of irradiated ergosterol in oil, containing from 20,000 to 100,000 times the necessary curative dose daily. The experiments lasted for 1 month, with weighings at weekly intervals. At the end of the experiment all animals were autopsied and blood analyses made. The animals fed irradiated ergosterol lost weight, suffered anorexia and general physical impairment. Growth was less than in either of the other groups, and the blood calcium concentration was 50 per cent higher than the controls. Bones of all animals appeared healed. The results indicate the possibility of harm by the use of excessive doses of irradiated ergosterol in rachitic animals. —Irwin J. Klein, *J. A. M. A.*, 92: 621 (Feb. 23), 1929.

Possibility of Infection from Bacillus Botulinus—This editorial recites the present known facts on *B. botulinus* and the possibility of its causing infection. Botulism is caused by toxins produced by types of *B. botulinus* developed in understerilized preserved foods. Because of the resistance of the spores the problem of adequate sterilization is important. The question as to the possibility of the germination of spores in the animal body has been investigated by Coleman and Meyer (*J. Infect. Dis.*, 31: 644 (Dec.), 1922), who found evidence of such germination in the closed jugular vein in laboratory animals. Recently with the use of formaldehyde to debilitate tissues, 25 spores inoculated intramuscularly grew and produced poison. Geiger showed that botulinus toxin was absorbed from fresh wounds with symptoms and death from botulism. In spite of the experimental evidence, no reports are available of human botulism from spore-contaminated wounds. It is suggested that public health officials should insist that spoiled food be destroyed and not consumed even after boiling. Such advice seems to be supported by the known wide distribution of *B. botulinus* as a soil organism.—Editorial, *J. A. M. A.*, 92: 563 (Feb. 16), 1929.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

The Baffling Problem of Maternal Mortality—One of the most baffling and distressing problems with which he has to deal, according to Mr. Chamberlain, the English Minister of Health, is maternal mortality. Speaking recently in connection with a mother saving campaign, he pointed out some of the efforts which are being made to promote maternal and child health in England and the lack of success in certain directions.

England spends annually out of public money about 10 million dollars on maternity and child welfare services. Voluntary agencies, in addition, spend large sums. Yet the maternal mortality shows no significant change. The total infant mortality has dropped during the last 22 years from 132 per 1,000 live births to 65. Mr. Chamberlain, with a restraint worthy of emulation by some public health workers on this side of the ocean, does not claim that this drop has been due entirely to child welfare activities, though he does think that the latter played a considerable part.

The maternal mortality, on the other hand, has remained almost stationary for the last 20 years or more, any tendency to change being in the upward direction. It appears extraordinary to the Minister of Health—as indeed it does to all thoughtful observers—that this condition should persist despite all the advances made in recent years in medical science and all the effort and money expended on antenatal and postnatal clinics, the training of midwives, and on propaganda generally. One of the obvious reasons for the maternal mortality is puerperal septicemia which as yet is often not preventable.

An interesting and hopeful statement made by the minister was to the effect that he had initiated an inquiry into the circumstances of every current maternal death, a study which would be carried on by a committee of experts. The interest of local authorities and the medical profession has been enlisted in the gathering of data.—London Letter, *J. A. M. A.*, 92, 13: 1136.

The Washington (D. C.) Child Research Center—In these days of belief in early health education it is interesting to hear of such a venture as this. The purpose of the Research Center, as stated, is " the experimental investigation of normal and problem children, with emphasis upon the development of the preschool child." Classification of the work is quoted in full:

1. Study of the training of preschool children
2. Study and treatment of problem children under 10 years of age
3. Parent education by means of individual conferences, lectures, group conferences, study classes and directed reading
4. Directed observation and study of preschool children by students in home economics
5. University classes in child development for undergraduate and graduate students
6. Coöperation with institutions caring for children in outlining their programs

A few of the problems studied so far —the center began work February, 1928 —are the incidence of colds in preschool children and effect of exhibition of hexyl-resorcinol upon their prevention; effect of muscle training upon flat feet and posture; influence of activity (play) and personality upon the duration and character of afternoon sleep, etc.

A parent education program is being

developed, which certainly seems a step in the right direction. Few "problem" children are unaccompanied by "problem" parents and this appears to be largely due to our inadequate educational methods.

Technical articles, popular pamphlets and a book, *The Process of Human Behavior*, are some of the publications of the center to date and will doubtless have much of value for all interested in the "neglected age."—Mandel Sherman, M.D., Ph.D., *Child Health Bull.*, Jan., 1929.

Mental Hygiene in the Public Schools—How mental hygiene may be made available and practical in our school systems is a question of great interest. Ira S. Wile, M.D., says:

Mental hygiene is a term that is frequently misunderstood as referring primarily to the problems of mental defectives. Wherever there is mentality, there is necessity for mental hygiene; wherever there are schools, mental hygiene exists; but there is considerable difference between mental hygiene that is helpful, constructive and effective and that which is poor, inadequate and disadvantageous.

Mental hygiene is merely the science and the art of preserving mental health and of preventing mental inadequacy from any and every cause, so far as may be possible.

It is patent that public schools cannot escape the implications of responsibility contained in this form of definition. *Who goes to school?* The child. He goes with his body, his mind and his soul. The entire child is at school.

Whether desired and purposed or not, every element that is placed into a school system has a positive, neutral or negative value for mental hygienists.

The school systems must recognize that all children are not cast in the same mold. The school has been wont to dwell upon intellectual deficiencies without adequate recognition of emotional disturbances. The average school program of today, in the light of our present knowledge, is unbalanced, because it is insufficiently influenced by the principles that are known to affect the personality of school children.

The child at school is in a dual position. He is his unit self and again he is a unit of any one of a large number of groups, such as his own class, several different departments and the school as a whole. The variations between individual desires and group demands afford abundant opportunities for emotional distresses and conflicts.

It is time to begin the consideration of mental hygiene, then, in its widest educational implications. As I view the subject, mental hygiene is inherent in every problem of education.

Dr. Wile makes certain suggestions as to a state program for mental hygiene within the school system:

The normal school for the training of teachers is a place of vital importance. Here the teacher should learn the organization of children's educational systems and their emotional reaction systems. She should have training in the purpose and interpretation of psychological testing and in methods of remedial teaching, and an appreciation of the specialized classes.

She should gain insight into her own difficulties. The personality of the teacher in the class room is always important. The unhappy teacher just "holding down" her job may do infinite harm.

It is important that the teacher see the mental hygiene potentials in the situation; the effect of success and failure, demotion, skipping a grade, failure in arithmetic, lax room discipline, etc.

Dr. Wile feels that a mental hygiene clinic available to the schools is a basic need. He suggests that on entrance to school each child be placed in a "clearing class" from which he should later be graded after study and size-up with the help of a visiting teacher; and further, an adjustment clinic made up within the school to study disciplinary matters. Discipline should not be punishment; it is guidance rather than a painful mandate. The offence should be viewed as symptomatic and its origin sought.

The combination of a clearing class, visiting teacher, and adjustment clinic would provide for the reasonable introduction of a constructive mental hygiene program into the public school system without great cost. Such a plan could be utilized in cities, large or small, and could be of great service without elaborate organization.—

Ira S. Wile, M.D., Mental Hygiene in the Public Schools; *Mental Hyg.*, XIII, 1: 70–80 (Jan.), 1929.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Post-Graduate Courses in Public Health Nursing—The Education Committee of the N. O. P. H. N. has continued studies of courses in public health nursing, and the report for the past year indicates that there are at present 11 courses in public health nursing meeting the approval of this committee and having the minimum requirements of "a qualified nurse director, affiliation with a school of collegiate grade, a budget, and academic year program with correlated didactic and field instruction."

In studying and grading the various schools, the aim of the committee has been to observe fundamental principles and leave the courses free to develop beyond that, as desired and as indicated by local needs.

Development of instruction and experience in mental hygiene, health education, school nursing and rural nursing are increasing. Some schools have received increased financial support. Closer coöperation between nursing departments and other departments in the colleges is being brought about. Efforts to correlate theory and practice continue to be made with varying degrees of success.

Seven of the 11 schools are connected with a 5-year university nursing program. The number of students enrolled in the schools and their academic and professional qualifications are steadily increasing, but progress would be brought about more rapidly if public health nursing agencies, particularly official health and educational agencies, would demand better qualified nurses.

The work of the Education Committee is to be greatly assisted in the future by the appointment of an educational secretary.—Gertrude E. Hodgman, Post-Graduate Courses in Public Health Nursing, Report of Education Committee of the N. O. P. H. N., *Pub. Health Nurse,* XXI, 2: 93 (Feb.), 1929.

Rural Public Health Nursing Teaching Centers—In the rural field, there is a need for more and better trained public health nurses, which is baffling rural public health nursing supervisors everywhere. Even in the 11 approved schools, the facilities for rural training are too limited to provide training for the rural nurse. Many must still be content with the experience secured on a city staff, however inadequate it may be in preparing them for the different psychological, administrative and health problems of the rural territory.

To meet this situation, certain rural training centers have been developed in different parts of the country without any particular plan of organization. About 8 of these have been studied, and the conditions in them present considerable variation. Some of these centers are under the direction of the state health departments in Alabama, Mississippi, Ohio and New York; some are rural fields used for experience of students in schools of public health nursing in Minneapolis, Minn., Cleveland, O., Richmond, Va., and Nashville, Tenn. Most of them have been selected because of convenient location; some because of good organization.

Advisory public health committees, which are recommended as essential to good administration by the A. P. H. A., were found to be functioning with varying degrees of success in some of the

places studied, while others had no such guidance.

The desirable length of time a student should remain in such a field is agreed to be about 2 months following appropriate theoretical courses, but actually the student's experience has varied from a few days to a few weeks. Much needs to be done to balance the student's experience and teaching in the essentials of office routine, community organization, child hygiene, contagious disease control, sanitation, clinics, group teaching and health education. Of course, much of the success or failure of these training centers will depend upon the personality and professional qualifications of the supervising nurse as well as the preparation of the students.

On the financial side, if the teaching program is well developed, it is sometimes found that students are an expense to the county organization, which must be met in some way. At present, in many instances, the students are receiving some salary for the service which they render during their period in the field.—Pearl McIver, Rural Public Health Nursing Teaching Centers, *Pub. Health Nurse*, XXI, 2: 72 (Feb.), 1929.

Guaranteed Annuities for Nurses—How shall we provide for the time when we are no longer able to follow our profession? This question has been one of the most perplexing in relation to nurses, and especially those engaged in private duty nursing. Inability to count on a secured income very far in advance because of irregular employment has prevented many private duty nurses from tying up their funds in large premium payments involved in the ordinary annuity policy.

A method of saving regularly in small amounts, in order to have an income in the later years of life, is one answer to the question and the solution to the problem for many nurses. The Harmon Association, 140 Nassau Street, New York, N. Y., has announced an annuity plan whereby registered nurses may deposit small sums monthly during their working careers and be assured a monthly income on reaching retiring age.

The fund is to be administered by the Harmon Association for the Advancement of Nursing, lately incorporated, and gifts may be made to the association by persons interested in swelling the annuities for nurses. A nurse may make a deposit according to her circumstances and when ready to retire may cease making payments and receive a monthly guaranteed income as long as she lives.

The plan has been endorsed by the officers of national nursing associations, representing about 100,000 nurses, and is similar to one worked out for teachers by the Carnegie Foundation for the Advancement of Teaching.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Dates Ahead—An encyclopedic help for those who wish to give a timely touch to publicity material or to plan events of timely interest is "Anniversaries and Holidays: A Calendar of Days and How to Observe Them," by Mary E. Hazeltine. American Library Association, Chicago, Ill., 1928. It lists birthdays of notable people, holidays, saints' days and other special occasions with information sources for many of them. Gorgas, Koch, Lister, Osler, Reed, Trudeau, and others are there. Numerous selected references are offered on amateur dramatics, pageantry, costumes, and so on. One method of use is to pick the man or the event you wish to use—in press releases, in a meeting, etc. Another possibility is to find the man or the event of interest to some organization in your community and propose some use by that group in which you can tie up some health message. *Price, $6.00.*

The Labor Blindness Prevention Campaign—An official letter from President William Green of the American Federation of Labor says:

As was announced to the New Orleans Convention, the American Federation of Labor has worked out with the National Society for the Prevention of Blindness a practical plan for a campaign to conserve eyesight. This plan includes the preparation of educational material and literature which will be printed in the *American Federationist* or in other labor papers.

The society is also prepared to send speakers to address labor bodies and meetings on the various phases of eye conservation. It considers this educational campaign of such great importance that it is willing to pay the expense of sending one of its officers or members of its executive staff to address special meetings of labor organizations where the educational effect will be far reaching. It would be necessary to allow at least 30 minutes for the address, and the speaker must be given a prominent place on your program. Of course, requests for speakers must be made far enough in advance to make possible the necessary travelling as well as to fit in with the itinerary of the various speakers. The National Society will also be glad to send to conventions of state federations or meetings of other large local groups sight conservation exhibits. It will also supply, without charge, a set of four large industrial posters with fliers. The society will also make available to unions selections from its collection of 500 stereopticon slides, charging only for transportation both ways and replacement of broken slides.

This coöperative project offers the possibility of numerous tie-ups for the alert state or local health agency. Write National Society for the Prevention of Blindness, 370 7th Ave., New York, N. Y.

Displays at San Francisco and Minneapolis—Classified displays of publicity and educational material will be features at the headquarters of the Social Work Publicity Council at San Francisco, Calif., June 26 to July 3. Especially for the sake of any Pacific Coast health workers who may not get to Minneapolis in October, it is hoped that many health items will be sent for display, and that health will be well represented in the prize awards for annual reports, feature stories, news photographs, posters, radio talks, and Sunday magazine articles. For details address the Council at 130 East 22d St., New York, N. Y.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

The President Recognizes Public Health—Several departments and other health agencies have quoted from President Hoover's inaugural address:

In public health the discoveries of science have opened a new era. Many sections of our country and many groups of our citizens suffer from diseases the eradication of which are mere matters of administration and moderate expenditure. Public health service should be as fully organized and as universally incorporated into our governmental system as is public education. The returns are a thousandfold in economic benefits, and infinitely more in reduction of suffering and promotion of human happiness.

"Do Not Kiss Me"—The baby bib has been enlisted for health propaganda by C. V. Craster, M.D., Newark, N. J., health officer. Bibs bearing these words, "Please Do Not Kiss Me—I Do Not Want to Get Sick," are sent to the mothers of new-born infants. It is a striking way of getting an idea over to mothers, and "it has given the mother a method of insisting on her baby's protection without incurring the hard feelings of her friends." Newspaper publicity has been widespread. A picture of the bib appeared in Hamburg, Germany. Letters have come to Dr. Craster from many cities in the United States and Canada from mothers, health officials, teachers, social workers and others. Sample from Department of Health, Newark, N. J., for 10 cents. Quantities with name of your department or association from Walsh Hospital Supply Co., Lincoln Park, Newark, N. J. 1,000 for $85.00.

Denver Survey Recommendations—The following recommendations for popular health education appear in *An Appraisal of Public Health Activities in Denver, Colorado:*

1. That, based on the needs outlined in connection with this study, a program of popular health education be planned, which will include as completely as possible the recommendations made by the committees dealing with the specific health activities, to the end that a well-rounded program may be undertaken and carried out.

2. That, since the newspaper is the most important medium for conveying information to the public, plans be worked out for the more general and regular use of the newspapers as a means of securing wide dissemination of information on health matters.

3. That, in addition to a more liberal distribution of pamphlets and bulletins on health, arrangements should be made for the establishment of a Speakers' Bureau, so that there will be available at all times some persons who are well qualified to speak on subjects relating to Public Health.

Specific recommendations for educational activities appear under "Venereal Disease Control," "School Hygiene," "Food and Milk Control," and "Heart Disease Control." A big job is laid out. There are no budgetary or personnel recommendations. Published by Denver Public Health Council. 50 cents.

Classification of Printed Matter—According to *Postage and Mailbag:*

If you will classify the various physical kinds of direct-mail according to their outstanding capabilities, they will fall definitely into these four groups:

1. *Continuity* (good will), house organ, mailing cards, booklets, pamphlets, package or letter inserts
2. *Action* (sales, inquiries), letters, all kinds, broadsides, self-mailing folders, unbound folders
3. *References* (information, data), catalogs, books, portfolios, maps, blue-prints
4. *Reminder* (name, location, business), blotters, calendars, post cards, novelties

Having this classification in mind, if you will decide what it is your proposed piece is to accomplish, you will have little trouble locating the format in one of these groups.

A "Hunch" for Editors—The following from *Editor and Publisher* (Mar. 23, 1929) might interest one of your local editors:

Those news editors who find their hospitals a difficult source of news might follow the example of a paper which recently carried a series of Sunday features describing one such institution each week, its history, et cetera,

illustrated with the cut of the present building, the superintendent and the head physician. The series supplied not only interesting reading matter but established good will with several important news contacts.

When a Governor Speaks—Governor H. H. Horton, of Tennessee, stated several major objectives of the State Department of Health in urging favorable action on the proposed budget of the department. The department will supply a copy of the statement.

HOUSE ORGANS

One of few house organs with a real community coverage, except the one so long issued by the Brookline, Mass., Department of Health, will be *Health News,* "Bellevue-Yorkville's Picture Newspaper." The first issue (see under "Diphtheria") was followed by one on tuberculosis. It is proposed to publish *Health News* monthly, with 40,000 copies to be delivered by a distributing concern. Copies of the first 5 issues will be sent as they appear for *25 cents* Address Marjorie Dent Candee, 325 East 38th St., New York, N. Y.

"Facts Taken from the Annual Report of Buffalo of 1857," in *Sanitary Bulletin,* Buffalo Department of Health, suggests interesting copy for use in many other cities.

Modern Health Crusader, 209 College St., Burlington, Vt., now appears in magazine size, with a stiff paper cover. "High School Revue" is a new idea for a special department.

SCAA News, New York, has been "dressed up" with new type—to increase attractiveness and readability.

Yours for Health is the new 4-page multigraphed monthly of the Racine Department of Health, taking the place of the former weekly mimeographed bulletin.

The *News Letter* of Dutchess Co. Health Assn., 16 Cannon St., Poughkeepsie, N. Y., goes monthly to 475 "doctors, nurses, board and committee members, supervisors and other good citizens of the country." The March, 1929, issue tells about the work done in getting out the *Letter* and asks readers to answer seven questions.

Will those who have asked readers what they thought about their organ, or what readers wanted to read, please report?

CAMPAIGNS

"To stimulate state-wide activity in child health improvement, the Indiana Child Hygiene Division is devoting 6 weeks to the initiation of health projects which will culminate on May Day." Details in *Monthly Bulletin,* Indiana State Board of Health, Jan., 1929. An elaborate program of possibilities. Includes questionnaire covering: health inventory, family, home, child, school.

"Putting On a Health Week," by E. O. Chimene. *Hygeia.* Mar., 1929. How Austin, Tex., did it. With organization chart.

SCHOOLS AND CHILDREN

"Danny Dentin in His Barrel" is a simple, home-made device invented by Neva Bushong, La Grange County (Indiana) nurse, to encourage correction of dental defects. Two sketches of "Danny" in *Echoes,* Indiana State Board of Health, Jan., 1929. *Free.*

Did you read "Candy—A School Health Problem" on page 69 of *Hygeia,* Jan., 1929, and also "Stalking the Food Faddist" by the Sugar Institute, on page 97?

For public and private schools having classes in French, pamphlets and other health material might be secured at reasonable rates from the Association de Propaganda pour la Protection Medicale et Hygienique de la Mere et de l'Enfant, 4, rue de Sevres, Paris, France. Price list upon request.

From the Shenango Valley Community Fund comes a story form which suggests possible uses by health work-

ers. "The Twins' Adventures in 'Heart Land'" opens as follows:

Jack and Marie were called "the Melville twins" by all who knew them. They were always (1) together, this brother and sister of (2) years.

"What shall we do today?" asked Marie of Jack, one (3) day in (4).

"Well," said Jack, "I see that the Community Fund is going to hold its annual campaign (5)."

On the last page are "Definitions of the Words to Put in the Blank Spaces," for example: (1) Viewed; (2) One dozen; (3) Not dark; (4) Tenth month of the year; (5) Fourth Monday in October to fifth Monday.

"The many requests received in our School Health Bureau indicate the need for definite and detailed descriptions of successful school health programs," says the Metropolitan Life Insurance Company. The response took the form of "A School Health Study of Newton, Mass." 88 pages. *Free.*

PUBLIC SPEAKING

"Whom Shall We Have as Speaker?" is the new list of topics and speakers offered to the public by the Speakers' Bureau of the Community Chest and Council of Social Agencies, 312 West 9th St., Cincinnati, O. Health topics are listed under "Health Programs and Problems," "Health Instruction," "Child Health," "Mouth Hygiene," and "Mental Hygiene." Some topics: "Next Door to Trouble" (by Chief Sanitary Inspector); "The Watchman at the Gate" (Chief Food Inspector); "Youth and Life and Commonsense" (Advisor for Girls, Woodward High School); "Fashions in Health" (Public Health Federation); "Beauty Products" (Nutrition Worker); "Tooth Truths" (Public Dental Service Society). Copy for *4 cents.*

Does the above prompt you to propose that a similar list be issued by the local chest or council of social agencies, or the group of local health agencies?

"A Public Speaking Clinic," in *Woman's Journal*, New York, N. Y. (Feb., 1929), describes a class and clinic conducted by a Los Angeles woman's club. To an increasing extent civic, social and health agencies are conducting classes or holding clinics in public speaking.

EDUCATION NEEDED

"The remedy for the menace of the quack in this field ('female cures'), as in all the other fields of quackery, is education. Women are gulled not because they lack intelligence but because they lack knowledge."—In "Female Weakness Cures," by A. J. Cramp. *Hygeia.* Mar., 1929.

HONORABLE MENTION

To California Department of Health: For detailed table of contents in Biennial Report.

To Pasadena, Calif., Health Department: For an annual report with an index, and an organization chart of the Department.

DO THEY NEED EDUCATION?

Note to teacher from parent: "If that nurse comes to school today to stick the children, send my children home. They wear asafetida to keep away diseases."—Reported by Nolan County, Tex., nurse while conducting a diphtheria campaign.

NEW PERIODICALS

Human Biology, Baltimore, Md., edited by Raymond Pearl.

Social Science Abstracts, Fayerweather Hall, Columbia University, New York, N. Y.

BOOKS AND REPORTS

Getting Ready to be a Mother—*(2d ed. rev.) By Carolyn Conant Van Blarcom, R.N. New York: Macmillan,* 1929. 286 pp. Price, $1.75.

This manual for mothers is a handy little volume, well printed on good paper and with many excellent cuts. The first edition appeared in 1922.

A book like this is presumably of most use to well-to-do, educated women. It would seem rather "highbrow" to the prospective mother with a grammar school education only. Furthermore—to give the unfavorable criticisms first—the book goes into too great detail in places, especially for the patient who is going to take the excellent advice given of engaging a physician early and following his directions. It is a question how much value there is to the amount of anatomy and embryology incorporated into chapters three and four. A little knowledge is often not only dangerous but upsetting and leads to morbidness, only too common during pregnancy. Again, the dietary advice in the later chapters is somewhat complicated and unduly restrictive.

It seems rather unwise to retail contradictory recommendations: it weakens the force of all. One should either lay down definite rules or else leave it to the physician to do. The fact that some physicians are said to advise so and so and others the opposite, leaves the poor patient, like the ass in the fable, not knowing which way to turn. Powdered milk is damned openly on page 196 and faintly praised on page 197, rather without justification in the light of more recent studies. Pasteurization, too, is treated in rather stepmotherly fashion.

One is a bit surprised to find little or no reference to the part that the visiting nurse may play as contrasted with the nurse who devotes her whole time to the one patient. There might be, with advantage, a little greater stressing of the vast importance of attention to diet during the prenatal period if the baby is to have proper teeth.

On the whole, the book is a most useful one and justifies its continued popularity. Its shortcomings, few in comparison with its strong points, have their roots in a desire on the part of the author not to trespass on the rôle of the attending physician—a rôle which he too often does not fill to the complete satisfaction of the anxious and inquiring patient.

It would seem that this book might be of value to nurses as well as to the more intelligent mothers, particularly in its chapters on the technic of the baby's toilet, and to most physicians too.

MERRILL E. CHAMPION

A Doctor's Letters to Expectant Parents—*By Frank Howard Richardson, M.D. New York: Norton,* 1929. 118 pp. Price, $1.75.

This series of letters is well written with an eye to answering the questions, spoken and unspoken, which trouble most prospective parents, fathers as well as mothers. It was a fine human touch to address some of the letters to both mother and father. The preface to the book rightly stresses this feature as more or less unique, as is also the emphasis laid on the psychological side of pregnancy—in many cases, quite the most important aspect.

Health departments more and more are using such letters to prospective mothers. The great difficulty they find is in preparing letters intelligible to the

less educated and yet not trivial in the eyes of the educated. Dr. Richardson evidently appeals to the latter class only; from the point of view of the purveyor of popular health literature his letters are decidedly "highbrow." On the other hand, they carefully avoid anatomical and physiological details which are unessential to the lay reader.

Certain especially good points may be referred to: a good talk to parents on the need of forbearance; another on the frank recognition of the drawbacks of pregnancy, both physical and emotional; "maternal impressions" is sensibly handled. There is sound advice about preparing the other children in the family for the coming of the new baby. Breast feeding, as one would expect from Dr. Richardson, is well handled.

One or two minor criticisms might be made. A little more detail might well be gone into concerning a well rounded diet. A rather unduly strong impression is left regarding the danger of attending to the mother's teeth late in pregnancy. Hospital care gets a little too much praise in view of statistical evidence of unfavorable mortality experience in hospital cases. The author runs up against the dilemma, inevitable when one physician gives advice to another physician's patients, of saying too little or too much: if he does not go into detail, the patient may not be told some essential things; if he does, he may be giving advice with which the family physician will disagree, leaving the patient wondering which is right.

On the whole, this little book will bring confidence and satisfaction to many a mother—and father, as well.

MERRILL E. CHAMPION

Children's Behavior and Teachers' Attitudes—*By E. K. Wickman. New York: Commonwealth Fund,* 1928. 247 pp. Price, $2.00.

The far-seeing public health worker is taking an active interest in the literature of mental hygiene and the problems of education. That many health programs (in the broadest sense) have failed in dealing with children of school age, has been due to lack of background on these two fields.

The present book is a very striking contribution to the literature of both mental and school hygiene (again used in a broad sense). Why do teachers consider certain pupils perfect blessings and other pupils, with different characteristics, the precise opposite? The truth is that teachers seem to set up standards of behavior which best meet their own comfort and happiness. That they favor the quiet, well behaved, even timid child would be obvious. On the other hand, the qualities of success seem to lie to a considerable extent in the very aggressiveness, or "attacking" personality, which teachers find disturbing to their discipline and displeasing to their personal preferences. That much good human material is lost through failure to recognize the seriousness of the "withdrawing" type of personality, and that such children are potential hermits unless changed into good social assets; loses prominence through the insidious peacefulness of the school situation created by the withdrawing types of pupils. Nor will the "tiger tamers" and subjugators get the best results from the "attacking" type of children.

Teachers, more than parents, resist attempts to modify behavior patterns because both their professional pride and their self-respect are involved.

Other blocks to progress among teachers are strong present habits, lack of opportunity to practice new procedures, and strong emotional and social maladjustment to the very problems which arise to distress adults in the behavior of children. The teacher's whole philosophy of life, every attitude, is reflected in behavior, and many a teacher is maladjusted. The answer is in the

study and treatment of behavior problems of children, with every classroom a laboratory.

The author leaves one with the impression that teachers as a class can scarcely be considered leaders; that they would do well to "cast out the mote" in their own eyes; that they must spend far more time and thought in professional improvement, at least along lines of social adjustment problems. It might be well to contemplate, in a broader view of the situation, just why many teachers are socially maladjusted. Are they so when they enter the profession? or does the profession in some way change them? The reviewer has his own theory based on studies made in New York State some years ago.

At any rate, this report of a well planned and adequately completed piece of research, is worth the careful attention of anyone who is, even in the vaguest sort of way, in contact with public schools—and that means most of us in the health field.

HUGH GRANT ROWELL

Your Teeth—*By Charles I. Stoloff, D.D.S. New York: E. P. Dutton,* 1928. 224 pp. Price, $2.50.

The cover makes a good impression. It looks like last month's contribution of the Literary Guild. Its wide margin and novel-like proportions keep up the illusion.

The title might well be "Your Teeth, Past, Present and Future," for Dr. Stoloff, though he includes the care of children's teeth, is thinking of the reader as an average American adult with a badly crippled dental machine in constant need of repair and possibly replacement in the future. It is perfectly true that practically all of the popular dental literature written to date is concerned with the child and the prevention of dental troubles. Dental health workers who have felt that the present generation was hopeless, dentally speaking, will be startled by the frankness with which Dr. Stoloff presents the opposite viewpoint on this question. It is also true that types of reparative work are seldom discussed by the average "family dentist." Most members of the dental profession have never felt it necessary to outline the advantages and disadvantages of a fixed versus a removable bridge, or a crown versus an inlay. Dr. Stoloff's point of view is well expressed in the following paragraph:

> An astonishing thing about the contemporary dental educational work is the utter lack of information to such unfortunates—and few of us there are who are not included—whose teeth require repairing or replacement, after the prophylactic (preventive) failure of the most rigid prescribed mouth hygiene. Why should there be more mystery about what is deemed good practice in reparative dental work, than what is considered to be good mouth hygiene?

The order in which the author presents his material is somewhat illogical, as the positive side of the picture, including general information on the two sets of teeth, their formation and care, is given before a discussion of treatment, removal and replacement and at the very end of a long description of root canal work, bridges and plates, appears Prenatal Care and the care of the mouth (tooth brushing)! Diet, though mentioned throughout, is formally introduced under Miscellaneous, with Halitosis, X-ray and Cancer.

Many disputed questions are answered by simple, clear-cut but conservative statements.

Much of the matter concerning the preventive side of mouth hygiene will be unsatisfactory to dental hygienists; for instance, the figure of tooth brushing on page 186, which shows the brush moving cross-wise over the teeth; and such advice to mothers, as on page 38: "If any cavity should form have it filled as soon as it is noticed." It is generally agreed that a mother should take her child to the dentist at frequent intervals (three or four months at this

age) whether she notices cavities or not.

The following, page 67, is surprisingly negative:

> Decay starts very frequently on the biting surfaces in the grooves (technically called fissures) because there may be minute cracks in the enamel at such points which make it difficult, or most impossible to clean thoroughly. Due to the frequency with which teeth decay in these fine "fissures" *there are dentists* who advocate drilling them out and filling them even before any visible evidence or sensation gives warning that the teeth are decaying

in view of the fact that the American Dental Association passed the following resolution as far back as 1926:

> RESOLVED, that in the aim to attain prevention of systemic and dental disease—(a) No defect is too slight to receive definite attention. (b) The temporary teeth should receive as much care as the permanent ones in order to promote the proper development of the jaws and head, and to maintain function. (c) Particular care and attention should be given to developmental pits and fissures, whether occurring in primary or secondary teeth, or whether decay is or is not present.

The line drawings are a good feature and will help to make the book useful in clinics and schools as well as in the waiting rooms of dentists, where it most certainly belongs.

ELEANOR G. MCCARTHY

The Bureau of Dairy Industry. Its History, Activities, and Organization—*By Jenks Cameron. Baltimore: The Johns Hopkins Press,* 1929. 74 pp. Price, $1.50.

The fifty or more service monographs of the United States Government issued by the Institute for Government Research have been prepared according to a uniform plan, but they are written by different authors of various capabilities. The style of the writer of this particular monograph often makes the reader wince, for the author seems to suffer the delusion that he must be clever and fill up space with poor puns and esoteric expressions. He mentions the "ultimate ungodly hour of up-betimesism," whatever that means, and informs us that "the case against American cheese was as strong as the cheese itself." He employs words like "sanitational" and "dissemination al" which seem so far to have eluded the dictionary. The editor as well as the author is at fault for such slovenly writing, and incompetent editing is seldom excusable.

Despite the occasionally atrocious style and the careless editing, this small book is packed with useful information about an important federal bureau, and anyone interested in dairy work will find it valuable for reference and even perusal. In addition to the historical account of the development of the bureau and its activities, there is a description of its organization, and also appendices giving laws, financial facts, and other useful data. The book contains a good index and a fairly adequate bibliography. It is well printed, though one g l a r i n g error, "sport" when "spore" was meant, got past the editor and typographer. JAMES A. TOBEY

The Harvey Lectures—*Delivered under the auspices of the Harvey Society of New York, 1927–1928. Series XXIII. Baltimore: Williams & Wilkins,* 1929. 280 pp. Price, $4.00.

The Harvey Lectures have deservedly won their place in medical literature. The present volume is no exception to the high standard which has been consistently maintained. It contains eight lectures, all giving comprehensive reviews of important subjects. More of them concern new problems and methods than has been usual in the past. An address on Harvey given at a dinner in commemoration of the 300th anniversary of the publication of his epoch-making work is included. Only one of the lectures—that on tularemia—is of direct public health interest. All, however, are important and of unusual excellence.

The printing and make-up of the book are good. M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Darke County, O.—This county health unit functions under a coöperative arrangement whereby the expenses involved are shared by the general district board of health, the city of Greenville, the State Department of Health and the Rockefeller Foundation. A total of 29,547 services were rendered, of which 19,707 were in the county area, and 9,840 in the city. Nursing home visits numbered 6,162, including, among others, prenatal, maternity, infant, preschool, tuberculosis, school and communicable disease visits. There were 9,877 services rendered by the inspection division.

Sanitary and health surveys were completed in 6 incorporated towns and in the 20 townships of the general districts. Every house in the city of Greenville and the 18 incorporated towns, and every farmhouse in the county was visited. In conjunction with the county unit, a training station for health workers has been maintained throughout the year by the Rockefeller Foundation and the State Department of Health. For every $100 spent from tax funds in the county district, 56 cents were spent by the Board of Health. The total expenditures for the year by all agencies amounted to $35,900, including expenses for the maintenance of the training station.

Lincoln, Neb.—Lincoln's 1928 report indicates certain changes in organization of a progressive nature. The child welfare bureau and pediatric clinic have been placed in the hands of a deputy superintendent and pediatrician. A general clinic is in the hands of a deputy superintendent and only those patients above 14 years of age are there treated. Tuberculosis patients are treated in both the pediatric and general clinics. A public health and obstetrical nurse have been added to the health staff. On the basis of a population of 70,000, a birth rate of 13.2 and a general death rate of 12.3 were recorded.

Walla Walla, Wash.—The annual report of the city and county health department for the year ending May 31, 1928, indicates a population of 28,130, a birth rate of 14.01, and a crude death rate of 13.21, with an infant mortality rate of 44. The average age at death for the year was 57. During the year, 57 per cent of the births and 42 per cent of the deaths occurred in hospitals. A card index is kept of all communicable diseases, and of the vaccination and diphtheria immunization records of each public school pupil.

The Commonwealth Fund—Appropriations totalling $2,083,622 were made by the Commonwealth Fund last year in furthering a wide range of public health, mental hygiene, child welfare and educational activities, according to its tenth annual report. Modern fifty-bed hospitals have been awarded to 5 communities since the beginning of the Fund's rural hospital program, for which $358,438 was appropriated during the year. The first of these was opened in Farmville, Va., in November, 1927. The institutions in Glasgow, Ky., and Farmington, Me., will be completed this spring, and those in Beloit, Kan., and Wauseon, O., will probably be opened before the end of 1929. According to the report:

> The rural hospital program is an experiment in social organization involving much more than a building project; it is an effort to attack from a fresh angle the difficult problem of medical and public health service in small towns and the open country, and to change

community standards in respect to the care of the sick, the prevention of disease and the protection of health.

Typical of the general program is the work now going on in the district of 9 Virginia counties served by the Farmville Hospital. The State Health Department has organized this territory into a single unit with a district health officer, under whose leadership a comprehensive health service is being gradually developed. Two medical institutes have been held, with clinical demonstrations and lectures on chosen topics. Ten local physicians have been awarded fellowships for brief postgraduate courses at well-known medical centers. The hospital itself is proving its usefulness to the community and has been operated under the direction of the local Board of Trustees on a gratifyingly high standard. As with all hospitals constructed under the Fund's cooperative program, a third of the cost of the building and equipment and the entire expense of administration have been assumed by the local community.

Experience in carrying on for the past six years a program for the development of child guidance clinics and visiting teacher service in the public schools has brought the conviction that the greatest present need in this field is the adequate training of sufficient personnel. The Fund's chief contribution toward meeting this need has been the Institute for Child Guidance, opened in New York City, July 1, 1927, and now in its second year of operation as a clinic and training center. The student group now includes 7 psychiatrists, 5 psychologists, and 44 psychiatric social workers who are specializing in work with children. For several years the Fund has assisted in a program for the development of child guidance clinic work in England. A special service and training clinic will be opened in the spring of 1929 under the auspices of the Child Guidance Council of Great Britain.

The program of five-year demonstrations of child health work which the Fund undertook in 4 American communities is drawing to a close. The work in Fargo, N. D., was completed at the end of 1927 and full reports of the results have been published during the past year. The demonstrations in Rutherford County, Tenn., and in Athens and Clarke County, Ga., ended in December, 1928. The work in Marion County, Ore., is entering upon its final year. Local appropriations and arrangements for carrying on all essential activities at their own expense have been made in these communities. In Rutherford County, particularly, the report finds " an outstanding example of the possibilities in public health created in a rural community by an awakened public conscience."

On July 1, 1929, the Fund expects to complete the program of child welfare and public health work in Austria which it took over in 1921. The various child health stations will be continued by the Austrian authorities, a new emphasis is being placed upon the adequate training of personnel, and the whole program promises to be successful beyond the hopes that were entertained when the work was begun.

Among the 43 special grants made by the Fund for public health, mental hygiene, and miscellaneous welfare projects during the year, the following may be noted: to the American Public Health Association for the study of public health programs in rural areas; for fellowships in psychiatry at the Boston Psychopathic Hospital, the Henry Phipps Psychiatric Clinic at Baltimore, and the University of Colorado Medical School; to the National Conference of Catholic Charities for a study of child caring homes; to the Boy Scouts of America for a study of the effects of scout work in a number of American cities; to the New York Tuberculosis

and Health Association for cardiac research; and to the American Forestry Association for a program of education looking toward the conservation of forest resources in three southern states.

Orange County, Calif.—This county has an area of 800 sq. mi. and an estimated population of 135,000, according to the 1928 report. The school population of the territory registers 21,387. A general death rate of 8.9 and an infant mortality rate of 73.5 are reported. Heart disease was the cause of death in 1 out of 5 instances.

Present-day preventive medicine is recognizing that it has a nation wide problem in heart disease, and is trying to meet this problem by urging upon the public frequent and regular physical examinations in the physician's office and at school, in order that heart maladies may be found early and perhaps remedied or at least protected from strain before a permanent injury has resulted.

During the year 3,992 complete courses of toxin-antitoxin were administered, 10 per cent being among preschool children. There were 16 cases of typhoid fever, but no deaths. A tuberculosis death rate of 73.8 per 100,000 population is noted. Sixty-nine new cases were reported during the year. Fourteen diagnostic clinics were held, and 468 examinations were made. Thirty-four patients are hospitalized in the new tuberculosis pavillion at the County Hospital and 29 under-nourished children are in attendance in the all-year health camp and preventorium maintained in the Santiago Canyon by the County Tuberculosis Association.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

International Public Health—A report of the session of the International Office of Public Hygiene which includes a consideration of the world-wide aspects of venereal diseases among seamen, yellow fever, plague, and outbreaks of other communicable diseases, infant hygiene, etc.

ANON. Regular Session of the Permanent Committee of the International Office of Public Hygiene, Oct., 1928. Pub. Health Rep., 44, 13: 711 (Mar. 29), 1929.

Health Guidance for Girls—An account of the "Girl's Health Trail" designed to focus attention upon tuberculosis in girls of high school age and to stimulate health habits. The machinery developed to carry out the plan in Wisconsin is described.

ANON. Wisconsin Girls Hit the Trail. Survey, 61, 12: 809 (Mar. 15), 1929.

Cancer and State Medicine—Dr. Bigelow tells of the work of the Massachusetts cancer program and makes it the basis of a plea for the medical profession to join with the health officer in solving the inadequacies of present-day treatment facilities—all done in Dr. Bigelow's inimitable way. It should be read by every health worker.

BIGELOW, G. H. Is the State's Cancer Program State Medicine? New England J. Med., 200, 9: 438 (Feb. 28), 1929.

Venereal Disease in New York—Another incidence study of venereal infection, this time in two counties of New York City (Staten Island and Brooklyn). The remainder of the city is to be reported upon later.

BRUNET, W. M. Venereal Disease Prevalence in the City of New York. Long Island M. J., 23, 2 and 3 (Feb. and Mar.), 1929.

Vitamin B in Infant Feeding—Some substance containing vitamin B should be added to the infant's diet just as orange juice and cod liver oil are added to supply the other vitamins. Wheat-germ sugar is the substance recommended to supply the vitamin B factor. Pity the poor yeast advertiser!

DENNETT, R. H. Routine Use of the Vitamin B Factor in Infant Feeding. J. A. M. A., 92, 10: 769 (Mar. 9), 1929.

Measles Serum—Dr. Ferry reviews the evidence which confirms his belief that measles is probably caused by a pleomorphic streptococcus.

FERRY, N. S. Etiology and Specific Treatment of Measles. Am. J. Dis. Child., 37, 3: 572 (Mar.), 1929.

Cleanliness—Practically a poem in praise of cleanliness, this British paper extols cleanliness of the skin, cleanliness of the air, cleanliness of food and water, cleanliness of soil (including our old friend "effluvia"), cleanliness of dwellings and streets. In conclusion, the reader is informed that it is the true basis of all health conservation.

HILL, A. B. Cleanliness: Is It the Basis of Health? J. Roy. San. Inst., 49, 9: 571 (Mar.), 1929.

Minerals in Nutrition—An excellent summary of the rôle of calcium, phosphorus, sunlight, irradiated foods, ergosterol, and the like, written especially for nurses. The article should be of value to health officials who are concerned with health promotion but who are not conversant with the details of research in nutrition.

KOEHNE, M. The Mineral Requirements of the Body. Pub. Health Nurse, 21, 3: 125 (Mar.), 1929.

The Burden of Heart Disease—Heart disease, in terms of incidence and death and loss of means of livelihood, falls more heavily on the underprivileged man and woman than upon the higher social levels. The burden is greater than in all other diseases except tuberculosis, mental defects and chronic arthritis, and increases with each decade in life from 25 to 65.

EMERSON, HAVEN. Economic Aspects of Heart Disease. Am. Heart J., 4, 3: 251 (Feb.), 1929.

Marriage and Divorce—Health officials will be interested in this statistical summary of divorce, if for no other reason than that they are the keepers of vital statistics. But all will be stimulated by the author's philosophical discussion. One observation is priceless. He says: "The obligation accepted at marriage for better or for worse . . . may be more correctly interpreted as for better or for divorce."

HOFFMAN, F. L. Marriage and Divorce. J. Social Hyg., 15, 3: 129 (Mar.), 1929.

Typhus Fever—A method is proposed for distinguishing the American strain of typhus fever (Brill's disease) from old world typhus. Formerly there was no immunologic distinction between the two forms.

MAXCY, K. F. Endemic Typhus Fever of the Southern United States: Reaction of the Guinea Pig. Pub. Health Rep., 44, 11: 589 (Mar.), 1929.

Typhoid Fever Outbreak—Another typhoid fever outbreak traced to chicken salad infected by a carrier. It was served this time at a wedding breakfast instead of the usual harvest home or church supper.

MINER, H. E., and FORSBECK, F. C. An Outbreak of Typhoid Fever Traced to Chicken Salad Infected by a Carrier. New England J. Med., 200, 9: 440 (Feb. 28), 1929.

How to Reduce Maternal Mortality—The continued high maternal mortality rate, higher in cities than in rural regions, will be lower when we have better obstetrical training for physicians, midwives and nurses, says this author. A more widespread knowledge and a clearer understanding of the importance of proper maternity care is also mentioned.

RICE, F. W. The Problem of Reducing Mortality Associated with Childbirth. New York State J. Med., 29, 5: 262 (Mar. 1), 1929.

Fatigue in Industry—The effect of fatigue upon the health and life of industrial workers and the influence of heat upon fatigue are discussed. The experience is with miners and steel workers in Great Britain.

VERNON, H. M. The Fatigue of Heavy Industrial Work, and Its Influence on the Health and Duration of Industrial Life. J. State Med., 37, 3: 141 (Mar.), 1929.

Irradiated Ergosterol—Another study indicating the value of irradiated ergosterol in the treatment of rickets. A commercial preparation was used and proved to be well tolerated and effective.

WILKES, E. T. The Treatment of Rickets with Irradiated Ergosterol. Am. J. Dis. Child., 37, 3: 483 (Mar.), 1929.

Rats on Shipboard—All about rats, their fleas, and the rat proofing and fumigation of ships.

WILLIAMS, C. L. A Rat and a Rat-Flea Survey of Ships at the Port of New York. Pub. Health Rep., 44, 9: 443 (Mar. 1), 1929.

Glass Transmitting Ultra-violet Light—Experience with two types of glass permitting the passage of ultra-violet rays, "Corex" glass and "Vita-glass," indicated the superiority of the former.

WYMAN, E. T., et al. The Value of Different Types of Glass for Transmitting Ultra-violet Light. Am. J. Dis. Child., 37, 3: 473 (Mar.), 1929.

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

THE following universities and technical schools are offering courses in public health and preventive medicine during their summer sessions. While this is not a complete list of schools giving such courses during the summer, it represents those replying to a questionnaire from the American Journal of Public Health and The Nation's Health.

UNIVERSITY OF CALIFORNIA, Berkeley, Calif. July 1–August 10
Social Hygiene
Child Welfare
Health of the School Child
Introduction to Statistical Method
Subject Matter and Technique in the Teaching of Home Hygiene and Care of the Sick
Preventive Medicine
Public Health Nursing
Administration of Schools of Nursing
Supervision in Schools of Nursing

UNIVERSITY OF CHICAGO, Chicago, Ill.
June 17–July 24 (First Term)
July 25–August 30 (Second Term)
Hygiene and Bacteriology
Public Hygiene
Immunity in Relation to Preventive Medicine
Public Health Problems
Sanitary Surveys
Public Health Nursing
School Hygiene
Physical Education
General Bacteriology
The Pathogenic Bacteria

RADIO PROGRAMS ON UNIVERSAL SAFETY

THE National Broadcasting Company, in coöperation with the National Safety Council, is giving a series of weekly radio addresses by national leaders on "Universal Safety." The purpose of this program is to awaken the American people from an attitude of seeming indifference toward the problem of the national accident fatality toll, numbering nearly 100,000 lives annually. Charles M. Schwab gave the first address, "Safety as a Factor in Industry," on April 20.

NEW ENGLAND HEALTH INSTITUTE

THE seventh annual New England Health Institute, a school of public health open to all public health workers and those interested in public health, was held in Hartford, Conn., the week of April 22–26, 1929. The Institute was sponsored by the U. S. Public Health Service, the Medical Schools of Harvard and Yale Universities, New England colleges, and state departments of health. The program of 84 lectures on the outstanding phases of public health was given by experts in their

respective fields. The fiftieth anniversary of the Connecticut State Department of Health was celebrated by a banquet at which the speakers were: Hon. John H. Trumbull, Governor of Connecticut, Dr. Edward K. Root, Dr. Hugh S. Cumming, Surgeon-General, and Dr. George E. Vincent, President, Rockefeller Foundation.

NEW MIDWESTERN FOOD OFFICIAL

JAMES O. Clarke has been appointed to succeed E. H. Goodnow, resigned, as chief of the Central District of the Food, Drug and Insecticide Administration. Mr. Clarke will direct the work of enforcing the food and drugs act and five other regulatory acts throughout the middle western district from his headquarters at Chicago.

Mr. Clarke has been in the service of the Department of Agriculture since 1917; first in the capacity of a chemist, having previously gained considerable experience in food analysis as assistant to the state chemist of Georgia. For six years he was chief of the station at Savannah, Ga., and in 1926 became chief of the New York station of the Eastern District of the Food, Drug and Insecticide Administration.

THE DIPLOMATE—A NEW PUBLICATION

THE first issue of a new medical periodical, *The Diplomate*, appeared April 3. This magazine is intended primarily for medical students, hospital internes and premedical students, and aims to keep them in touch with medical news and developments, especially in regard to medical colleges, preventive medicine and public health, the state licensing boards and the organized medical profession.

REMINGTON MEDAL AWARD

DR. Wilbur L. Scoville, chief of the analytical department of Parke, Davis & Co., has been awarded the Remington Medal by the American Pharmaceutical Association. The medal was awarded for "distinguished service to pharmacy," as chairman of the National Formulary Committee.

SPECIAL CHILD HEALTH TOUR

IN connection with the meeting of the Health Section of the World Federation of Education Associations in Geneva, Switzerland, next summer, a special tour for the study of child health activities in Europe is being arranged. This tour is for people professionally interested in child health, particularly school health. The dates of the tour are June 29 to September 1. Persons interested in joining this group should write to Professor C. E. Turner, Massachusetts Institute of Technology, Cambridge, Mass., who is chairman of the Health Section of the W. F. E. A.

EAR, NOSE AND THROAT STUDY

THERE will be an Ear, Nose and Throat Course, for American physicians only, at the University of Bordeaux, France, commencing July 22, 1929.

Dr. Leon Felderman, Philadelphia, Pa., is in charge of registering the American physicians.

HEALTH SCOUTS IN PALESTINE SCHOOLS

SCHOOL children in Palestine have been organized as sanitary inspectors to help raise the country's standard of public health. Their tasks are to safeguard the hygienic and sanitary conditions in the schools; help the school nurse in her teaching of hygiene; and to influence the homes in accordance with modern scientific regulations taught them by the department of hygiene. The health scouts visit dairies and food shops, submitting reports to the department.

PERSONALS

JESSE L. MEGARGEL, of the Hammonton, N. J., Board of Health, has been awarded the Anderson Memorial Gold Medal for distinguished services to the community along the lines of diphtheria prevention.

DR. JOHN J. SIPPY was elected president of the Northern California Public Health Association, succeeding Dr. William C. Hassler.

DR. B. S. STEPHENSON, Health Commissioner of Shelby County and Sidney, O., will attend the International Health Conference at Zurich in May.

DR. OLIVER KAMM, chief of the Chemical Research Division of Parke, Davis & Co., was elected president of the Michigan Academy of Science, Arts and Letters at its annual meeting held at the University of Michigan, Ann Arbor, during the third week in March.

DR. HUGH CARTER, of the Department of Sociology, University of Pennsylvania, has joined the staff of the Committee on the Cost of Medical Care, Washington, D. C. Dr. Carter has just completed a statistical study of Public Poor Relief in Pennsylvania since 1875 for the Commonwealth Fund and the Public Charities Association of Pennsylvania.

DR. DAVID KELLOCK, Health Officer of Harrisville, N. Y., died March 9 after a brief illness.

DR. AUGUSTUS MAYER, health officer of the town of Delaware, Sullivan Co., N. Y., died March 4.

DR. CALVIN L. COOPER has been appointed Health Officer of Kansas City, Mo., to succeed Dr. Porter E. Williams. His appointment will go into effect May 1.

DR. GEORGE F. REDDISH (Referee on Disinfectants of the Committee on Standard Methods of the A. P. H. A.), formerly Senior Bacteriologist in the Food, Drug and Insecticide Administration, Department of Agriculture, Washington, D. C., is now with the Lambert Pharmacal Co., St. Louis, Mo., as their chief bacteriologist.

DR. REGINALD J. H. STROUD was appointed State Superintendent of Public Health of Arizona by Governor Phillips.

ETHEL GROSSCUP is secretary of health instruction, Committee on Tuberculosis and Public Health, S. C. A. A., New York, N. Y.

CONFERENCES

May 7–8, Association of American Physicians, Atlantic City, N. J.

May 5–10, First International Congress of Mental Hygiene, Washington, D. C.

May 13–15, American Proctologic Society, Detroit, Mich.

May 14–17, American Psychiatric Association, Atlanta, Ga.

May 27–31, National Tuberculosis Association, Atlantic City, N. J.

June 13, International Hospital Congress, Atlantic City, N. J.

June 17–21, Annual Convention, American Hospital Association, Atlantic City, N. J.

June 24–28, American Water Works Association, Toronto, Can.

June 26–July 3, National Conference of Social Work, San Francisco, Calif.

July 8–13, International Council of Nurses, Montreal, Can.

July 9, American Heart Association, Scientific Session, Portland, Ore.

FOREIGN

May 15–20, International Congress of Public Health, Zurich, Switzerland.

July 13–20, Fortieth Congress and Exhibition of the Royal Sanitary Institute, Sheffield, England.

Training in Military Preventive Medicine*

GEORGE C. DUNHAM, M. C., U. S. A., M. D., DR. P. H.,
FELLOW A. P. H. A.
Director, Department of Sanitation, Medical Field Service School, U. S. Army, Carlisle, Pa.

THE prevention of disease and the promotion of health among its personnel is one of the most important activities of a war-time army. The day is past when an army can be mobilized, trained and successfully employed in combat unless every possible measure is taken to protect the health of the troops. The army consists of men drawn from all walks of life and from all types of environment. During and after mobilization, each individual is subjected to environmental conditions which, unless controlled, will entail a high degree of exposure to infectious disease.

The prevention of disease and the promotion of health in a military force are no longer considered on humanitarian grounds only, nor ignored when rendered inconvenient by purely military activities. Preventive medicine enters so intimately into all training and operation that it has become an essential military factor which must be provided for in all plans. No American army in the future can reasonably hope to defeat the forces of a first class enemy power if the troops are not given adequate protection against disease.

The health of a force can be protected and maintained only when the plans are formulated and carried out by officers trained in health work. It follows that in the event of an emergency which would compel the United States to engage in a major war, the control of disease among the troops must be accomplished mainly by men who are now working in the field of preventive medicine in civil life as physicians, engineers, technicians, research workers, and such. The

sanitarians of the Regular Army are few and could not possibly cope with the work that would be made necessary by mobilization. The National Defense Act provides for this contingency by authorizing during peace the organization and training of an Officers Reserve Corps.

The Medical Department Reserve has approximately 20,000 officers, organized into 5 sections: Medical, Dental, Veterinary, Sanitary and Administrative. The Medical, Dental and Veterinary Sections are composed of doctors of medicine, dentistry and veterinary medicine, respectively. The Sanitary Section consists largely of sanitary engineers, and experts in bacteriology, nutrition and metabolism, chemistry, and so on, with specialists in certain other lines not concerned with health.

The Medical Department is responsible to higher military authority for the initiation and supervision of all disease control and health promoting measures. Early in the World War it became apparent that officers trained in medicine alone were not equipped to solve many of the health problems requiring an expert knowledge of one of the allied sciences; consequently, steps were taken to commission in the Medical Department those having the required training. This group, with those commissioned since the World War, now constitutes the Sanitary Section of the Officers Reserve Corps.

The Medical Department officers who will supervise the health work and train others during any future war will be drawn largely from those in the Medical and Sanitary Sections of the Reserve who have had experience in preventive medicine. These officers will have received their basic training in medicine in the performance of their professional work in civil life. They must, however, receive a certain amount of training in military preventive medicine before they can function efficiently with a military force. This can be obtained either by organized training during peace or by the trial and error method after war is declared.

Military preventive medicine differs from that in civil communities in its administrative features, and to some extent in the means employed in the application of accepted procedures. It must be remembered that the primary mission of the army is to defeat the enemy and that all other functions and activities are subordinated to the accomplishment of that mission. A military force is a *machine*, each part of which must operate in coördination with all other parts. This does not mean that disease control measures can be neglected or ignored, as they are of vital importance to the success of training and combat operations. They must however be so adapted to existing

conditions as to afford the required protection with the least practicable interference with other activities. Military preventive medicine differs from that practiced in civil communities to an extent which renders it necessary for reserve officers, who are experts in their fields in civil life, to acquire additional training in order to apply successfully their knowledge to military conditions.

In the practice of military preventive medicine, measures must be adapted to, or modified to conform with, the restrictions and limitations imposed by a constantly changing situation. While military factors may at times prevent the adoption of a more desirable though more elaborate procedure, the administrative control of health is far more complete in a military, than in the average civilian, community. The extent of this control is such that the resulting protection in an army is, in general, much more effective than that in a civilian community, provided the officers in charge are conversant with the military phases of preventive medicine.

It is obvious that all reserve officers should receive basic military training in time of peace in order that they may be prepared to train other officers and enlisted men in the event of war. Under the provisions of the National Defense Act, such training is provided, including the organization and functions of military units and the strictly military features of the various services. While this is basically essential for those officers who are to be assigned to health work in the army, it does not prepare them for their special duties since it does not show them how their knowledge can be applied under military conditions.

Reserve officers, who are specialists in preventive medicine, will in most instances be assigned in war to duties connected with disease control and health promotion in the army. They should therefore receive training during peace-time in the military phases of their wartime duties. Basic military training, as described above, does not meet this need, and so special courses of instruction must be given.

Instruction of this character can be given in two ways under the schemes now authorized by the federal government. Selected reserve officers may be detailed to attend a summer training camp or they may be given correspondence courses. The summer training camp has the disadvantage of short duration—usually 2 weeks—and of occurring at a time when not all reserve officers can leave their normal vocations. It has the great advantage of bringing officers into personal contact with one another and with their instructors, and of making the training much more practical. Correspondence courses may be made quite extensive and inclusive in subjects which can be

taught by correspondence. They may also be undertaken when, and as rapidly as, the student has the available time. A disadvantage is the difficulty of imparting adequate instruction in certain subjects of a more practical nature.

Prior to 1928, no definite instruction in military preventive medicine had been offered to reserve officers, but for several years there had been an increasing demand for such a course. This was due partly to the progress in disease prevention, and partly to the growing realization of the important rôle which disease control will play in the next war. To provide a means for giving this instruction, an annual 2 weeks' summer camp course was established at the Medical Field Service School, Carlisle Barracks, Pa., from July 8 to July 21, 1928. This is known as the "Special Course—Military Sanitation," the term "Military Sanitation" being used to denote all phases of military preventive medicine.

Attendance is voluntary, selected officers who indicate the desire being ordered to active duty for training purposes. The 1928 class consisted of 46 reserve officers, members of the Sanitary and Medical Sections of the Medical Department Reserve. These officers, with a few exceptions, are in civil life engaged in work concerned, directly or indirectly, with the prevention of disease, and all would be assigned to disease control work if called to active duty. Some are sanitary engineers, others health officers of civil communities, specialists, research workers or teachers in such sciences as bacteriology, nutrition and chemistry. A number of them are widely known authorities in their particular fields.

The instruction given during the course is intensive and designed to emphasize the military aspects of preventive medicine. It consists mostly of practical demonstrations showing how the usual disease control procedures would be executed in given military situations. Didactic instruction is reduced to a minimum and discussions of technical procedures are limited to orientation and preparation for practical demonstrations. Methods of conducting sanitary surveys are demonstrated and instruction is given in the preparation and enforcement of the sanitary order (the sanitary code of a military community). Throughout, stress is placed on the administrative features of disease control and the practical methods of coördinating this work with other military activities. Much attention is devoted to the means by which coöperation between the Medical Department and other branches, both staff and line, is maintained for the purpose of protecting and promoting the health of the troops.

The application of disease control procedures in selected military

situations is considered for mobilization and training camps, concentration areas and camps, and the combat zone. Terrain exercises, in which the situation being depicted is simulated in the field, are utilized.

As the 1928 camp course was the first organized course of instruction in military preventive medicine given to reserve officers since the World War, it was in a way an experiment conducted to determine two important factors: (1) whether the reserve officers concerned desired this kind of training; and (2) if teaching the military phases of preventive medicine by a 2 weeks' summer training camp course is a practical procedure.

The type and number of reserve officers who took the course justifies the conclusion that training of this nature is desired by those interested in preventive medicine. This is an important factor as no scheme for the military training of the Reserve components of an army can be successful in peace if it is not supported by public opinion as expressed by the members of the group who are to be trained.

The experience gained definitely indicates that it is a practical method of teaching the military features of military preventive medicine, and that it will give results which are of great value to those taking the course. It offers what is apparently the best method at present of instructing reserve officers, and should prove a valuable contribution to military preparedness.

Juvenile Court Statistics in Belgium

THE number of cases handled by the juvenile courts of Belgium decreased from nearly 17,000 in 1913 to 11,000 in 1927, according to statistics published by Dr. Isidore Maus, Director General of the Belgian Child Welfare Office. This decrease has been particularly great and constant since 1920, and is attributed by Dr. Maus partly to the improvement of the economic situation of the working classes and the decrease in the birth rate during the war, and partly to the effect of the child welfare law of 1912, which provides for probation and other preventive and corrective measures.

The number of cases put on probation has shown a tendency to increase in the last few years. There has also been a considerable increase in the number of cases committed to specialized institutions. The number of cases referred to societies or institutions interested in general care of children has continued to decrease greatly.

The jurisdiction of the juvenile court ends at the age of 21. A follow-up study of nearly 10,000 former juvenile delinquents showed that between the ages of 21 and 26, 82 per cent had no conflict with the law.—*L'Application de la loi du 15 Mai 1912 sur la Protection de l'Enfance de 1913 à 1927*, Brussels, 1928, 27 pp.

The Sanitary Control of Ice Cream*

F. W. FABIAN

Department of Bacteriology, Michigan State College, East Lansing, Mich.

ICE CREAM is no longer considered a confection or luxury, but a food. Since it contains on the average approximately 22 per cent milk solids, it is a dairy product. It has won a high place in the American diet and is recommended by leading dietary authorities as an attractive way of serving milk to the family.

There is reason to believe that it was known in Europe as early as the 13th century and certainly in the 16th, though it did not assume the position it rightfully merits until recently. The ice cream industry as we know it today is a development of the last 25 years, during which time it has reached tremendous proportions, especially in the United States. This is due to several factors, the most important of which are its food value, modern machinery, and modern methods of merchandising.

It was estimated that the production of ice cream in 1927 in the United States was 335,703,610 gallons, a per capita consumption of 2.85 gallons. In 1910 the estimated production was 95,450,000 gallons. The capital invested in 1926 was estimated to be over $450,000,000.

METHODS OF SANITARY CONTROL

Milk, cream, condensed and evaporated milk, milk powder and butter are used in the manufacture of ice cream, and contribute by far the greater number of bacteria to it. Other constituents, such as gelatin, sugar and flavoring extracts, are used in such small quantities, or contain so few bacteria, that they may be left out of consideration. The fundamental problems of ice cream and milk control are the same.

To produce wholesome ice cream we must start with clean, raw products properly pasteurized and processed in clean machinery operated by sanitary workers. The requirements for milk for ice cream should be the same as those for market milk. The same sanitary safeguards should surround all dairy products whether they enter the ice cream mix or are used in some other way.

---

* Read before the Food, Drugs, and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

PASTEURIZATION

More interest is being shown in this phase of ice cream control than in the past. In 1926 a committee of this Association recommended legislation requiring nation-wide pasteurization of the ice cream mix. The manufacturers themselves are in favor of such action, as expressed by the Secretary of their association:

> Pasteurization of ice cream mixes should be made universally compulsive and it is interesting to see that so many states this year took action on this subject. The National Association is on record favoring pasteurization of the ice cream mix. It would seem desirable for state associations to encourage the passage of pasteurization laws in their respective states.

Activity has been manifested during the past three years in this direction. According to the latest information available 2 states and 1 province require the ice cream mix to be pasteurized; 11 states and the District of Columbia require the milk and cream used in the mix to be pasteurized. Some of the states require that all milk be obtained from tuberculin tested cows; prohibit the handling of ice cream by those having an infectious disease; and require a health certificate for those employed in making ice cream. These are necessary safeguards and should be included in any law governing the manufacture of ice cream.

As in the case of milk, the time and temperature requirements for pasteurizing the mix for the different states are variable, ranging from 140° F. for 25 minutes to 185° F. flash. This is unfortunate. After studying the results secured by one commercial plant over a period of years Fabian recommended a temperature of 150° F. for 30 minutes. Due to the nature of the product this higher temperature is necessary to insure proper results. The product is injured in no way physically.

Some laws require that only the milk and cream used in the manufacture of ice cream be pasteurized. It is much more satisfactory to require pasteurization of the whole mix, since it gives more uniform results and is in accord with the best practice of the industry.

TOOLS OF THE HEALTH OFFICER

In controlling the sanitary quality of ice cream the health officer has two effective tools—bacteriological analysis of the finished product, and sanitary inspection of the plants. It is recognized that while mere numbers of bacteria may not be significant from a sanitary standpoint, in the case of dairy products an excessive number is generally associated with carelessness. With proper care it is possible to produce ice cream with a bacterial count of around 100,000 per gram. A count greatly in excess of this may be due to any one or all of the

following: poor quality of ingredients, inefficient pasteurization, improper ageing, deficient cleansing of equipment, and carelessness of the employees.

Data have been assembled showing that it is possible and desirable to produce ice cream having a bacterial count of 100,000 or less per gram. Fabian has suggested a bacteriological standard of 100,000, based on 1,110 samples from 36 plants in 5 cities in Michigan.

Only one state has a bacteriological standard for ice cream. In 1927, California passed a law which states, "Ice cream, when sold by the manufacturer, shall not contain in excess of 150,000 bacteria per gram." Several cities have adopted bacteriological standards. Louisville, Ky., has a standard of 800,000 bacteria per c.c.; Harrisburg, Pa., 200,000 bacteria per c.c.; Concord, N. H., has a standard designating grade A ice cream, containing not more that 100,000, and grade B, containing not more than 1,000,000. Boston, Mass., limits the number of bacteria to 500,000 per c.c. Baltimore, Md., allows 200,000 at present, but its ultimate goal is 100,000. While Detroit, Mich., has no legal standard, its aim is to keep the bacteria below 100,000. Chicago, Ill., has a maximum of 500,000 bacteria per c.c. for pasteurized mixes, and no definite standard for the finished product, but requires that it shall not contain an excessive number.

I would suggest to those enacting laws or ordinances that "bacteria per gram" be used instead of "bacteria per cubic centimeter," since I believe that bacteriological determinations of ice cream made on the gravimetric instead of the volumetric basis will be more uniformly satisfactory. The gravimetric basis is used entirely for chemical determinations in ice cream and should be for bacteriological determinations. The volumetric method was inherited from milk analysis and is hard to get rid of.

Some progress has been made in standardizing the methods for analyzing ice cream. The committee appointed by the American Dairy Science Association has published a preliminary report,* and in 1927 the committee appointed by The National Association of Ice Cream Manufacturers made its first report, the two being in essential agreement. We now have outlined definite methods of procedure, among which are: the plate, direct microscopic, the methylen-blue test, and the anerobic spore test, recently proposed by Weinzirl and Harris. There has been some work on the colon group test. However, I do not believe that it has been sufficient to warrant any definite conclusions at this time.

* Copies of this report may be obtained from R. S. Breed, Ph.D., Geneva Experiment Station, Geneva, N. Y. Price, 25 cents.

A potent agency in the sanitary control of ice cream is periodic inspection. This has been found of benefit in other industries and has produced good results in the ice cream industry when consistently practiced. A great aid in the inspection of ice cream plants is the score card. The one with which I am more familiar is being used with success in several large cities. Periodic inspection plus regular bacteriological analyses will do much to keep a close check on the sanitary quality of the product.

WHY ARE SANITARY REGULATIONS NECESSARY?

Owing to a mistaken belief in the germicidal effect of cold, it was thought for a long time that bacteria present in ice cream would be killed by freezing and the subsequent process of hardening in which a temperature as low as — 21° C. was reached. Experiments have demonstrated that many of the pathogens are viable after being exposed to liquid air (— 182° to — 190° C.) for 7 days, and liquid hydrogen (— 252° C.) for 10 hours. It is well known that typhoid bacilli may remain alive in ice for a considerable time. Experiments have shown that they may remain alive in ice cream for 2 years and 4 months, when kept at an average temperature of — 4° F. Other work has demonstrated that hemolytic streptococci and the diphtheria bacillus may remain viable for considerable periods of time in ice cream.

Another line of evidence even more convincing is the numerous epidemics that have been definitely traced to ice cream. Fabian compiled a list of outbreaks attributed to ice cream, and since then reports of many more have been found, which will be published later. Epidemics of typhoid fever, septic sore throat, diphtheria, scarlet fever, dysentery and intestinal disturbances have been reported.

It is interesting to trace the history of ice cream epidemics. They can be grouped roughly according to the period in which they occurred. The first, extending from about 1848 to 1886, may be called the metallic poisoning period, since at this time they were attributed by most workers to poisoning from metals as tin, arsenic and zinc, while others were inclined to lay the blame on the vanilla extract used. The second may be desgnated the ptomaine poisoning era. In 1886 Vaughan discovered and isolated tyrotoxicon. Thereafter, for about 10 years, unless otherwise demonstrated, all ice cream poisoning was attributed to ptomaines. In the third period bacteria came into their own, and most of the epidemics have been definitely traced to a specific organism.

Today with the greatly improved machinery, and with our present

knowledge of sanitation and the application of science to these problems, there seems little excuse for an insanitary or unwholesome product. The ice cream manufacturers as a whole are far more alive to the best interests of their industry than any other group with which I am familiar. They kept abreast of the times and installed expensive pasteurizing and refrigerating equipment in their plants while many health officers were still slumbering. They did not wait for laws or ordinances requiring such action, but while the health officer was fearful about recommending such measures, they were obeying a more urgent law—the economic law. Experience had taught them that a sanitary product was their best business asset. One epidemic directly traced to a plant would tear down more than years of advertising could build up.

One of the finest tributes that can be paid to their good judgment is that, although more ice cream was manufactured in 1927 than ever before in the history of the industry, not one single epidemic was traced to it.

Italian Traveling Tuberculosis Dispensaries

TRAVELING tuberculosis clinics have been recently established in some provinces of Italy for the purpose of carrying medical aid to outlying districts.

Each traveling clinic consists of a large automobile containing equipment to aid in diagnosis of cases of tuberculosis, including a microscope and X-ray apparatus. A physician with two or more assistants is in charge of each.

Upon arrival in a district, the staff of the clinic examines the school children and advises the local authorities with regard to methods of dealing with those who have tuberculosis, such as providing financial aid and hospital and sanatorium treatment. Detailed records are made of each case.

Adults who are known to have tuberculosis, but who are not under medical care, are also examined at the traveling clinic, and provision for their treatment is made. The work of the traveling clinic in each district is concluded with a public lecture on tuberculosis given by its staff.

Recently the National Bureau of Public Health, in a circular addressed to local authorities, has recommended the introduction of such traveling clinics in the small towns and rural localities throughout the country.—*Difesa Sociale,* Rome, Sept., 1928, p. 11.

Nutritive Value of Ice Cream

L. S. PALMER, PH. D.

Professor of Agricultural Biochemistry, University of Minnesota, St. Paul, Minn.

ON theoretical grounds there is abundant evidence to support the belief that ice cream has a high food value. Food authorities and public health officials everywhere have recognized the importance of ice cream as a food, and there have been several more or less practical demonstrations of this fact with public school children. From a more strictly scientific standpoint Smith [1] has shown that ice cream contains the fat soluble A and water soluble B vitamins. However, no one has published data demonstrating under experimental conditions in what manner ice cream supplements a more or less natural diet of the bread, meat, potato and cereal type, during growth. Likewise, it is not known what kind of growth would result if the diet were limited exclusively to ice cream.

The experiment described in this report was for the purpose of answering these questions. It was conducted in the animal nutrition laboratory of the National Dairy Council, at Forest Lake, Minn. The animals used were albino and piebald rats bred in the laboratory. The ice cream used was standard commercial vanilla ice cream purchased in the local market, and was *not* manufactured especially for the experiment. The product used had a standard composition of 38 per cent total solids and 12 per cent fat.

Three types of diets were employed: (1) a basal diet containing no ice cream, (2) the same diet mixed daily with 33⅓ per cent by weight of fresh ice cream, (3) fresh ice cream alone without any other food. Fresh tap water was supplied daily, *ad libitum,* in syphon fountains attached to the outside of the cages. The all ice cream and the one-third ice cream diets were allowed *ad libitum.* The no ice cream basal diet was moistened with water to the moisture content of the one-third ice cream diet. The amount allowed was limited to that consumed by the group receiving one-third ice cream, this being determined each day. The ingredients of these diets are shown in Table I, and the approximate analyses in Table II. The basal diet was designed so that the supplementary effect of the vitamins in the ice cream would particularly be manifested.

The animals were housed in groups in suitable cages having metal

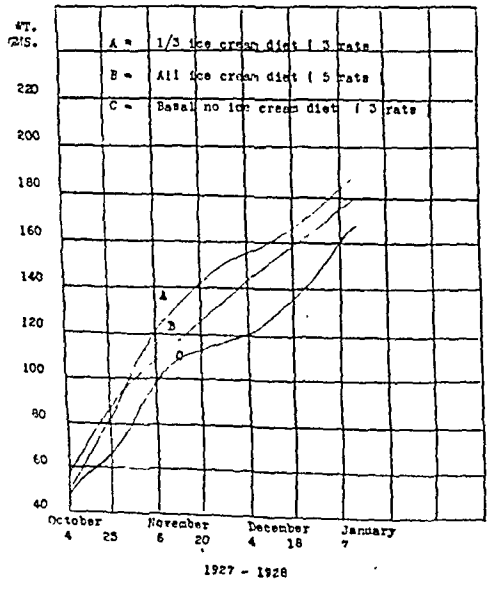

TABLE I

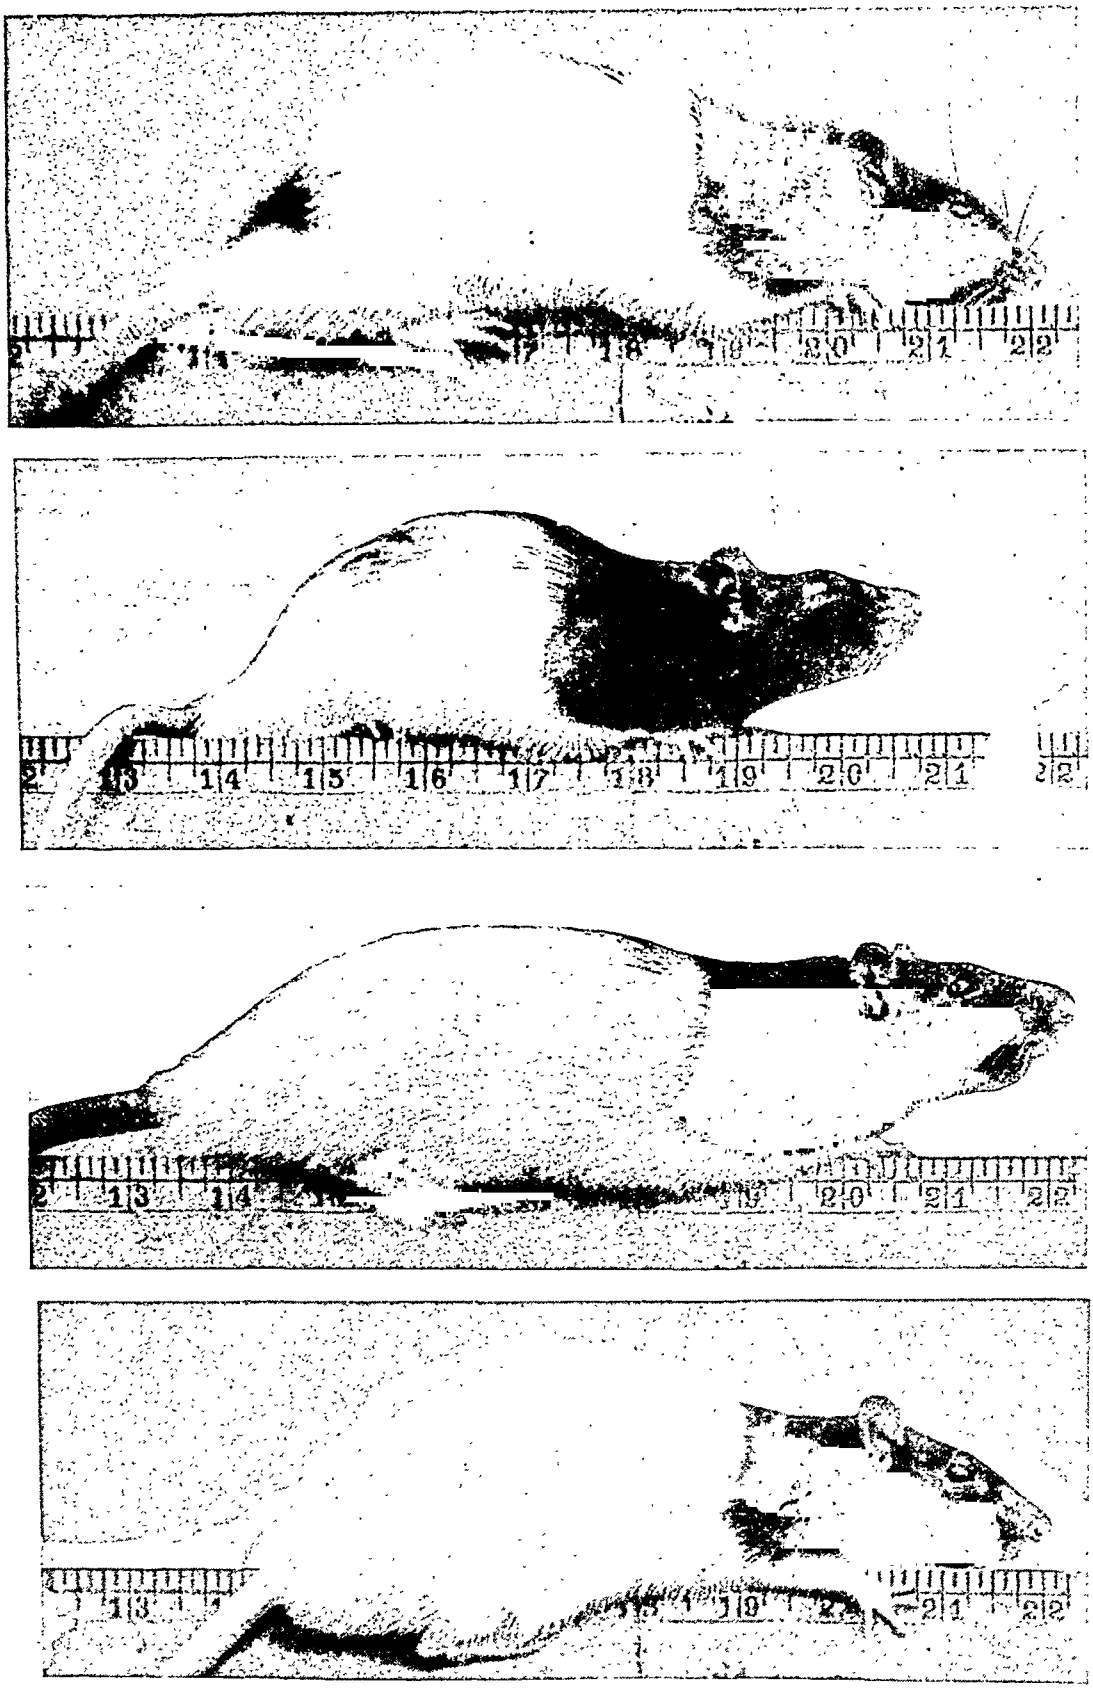
INGREDIENTS OF BASAL AND ONE-THIRD ICE CREAM DIETS AS FED



Ingredient	Basal Diet Per Cent	One-third Ice Cream Diet Per Cent
Ice cream	0	33.33
Added water	12.50	0
Dry bread	26.25	20.0
Potato flour	17.50	13.33
White corn	13.13	10.00
Extracted casein	7.87	6.00
Lard	7.00	5.33
Dry cooked beef	4.37	3.35
Oatmeal	4.38	3.35
Sugar	3.50	2.65
Bone meal	2.63	2.00
Salt	0.87	0.66
Total	100.00	100.00

floors covered with shavings. These were cleaned once each week and fresh bedding provided. Food consumption was recorded. The basal and one-third ice cream groups consisted of 3 rats each, and the all ice cream group of 5 rats. Bi-weekly weights of all animals were recorded for the first 90 days, the animals being placed on the diets at weaning, when they were 3 to 4 weeks of age. Males only were used. One group of litter mates distributed among the three experimental groups, and one other of the same litter on the breeding diet, on which similar records were kept, were continued on the diets until 44 weeks of age. These animals are shown in the accompanying photographs.

FIGURE I

The average growth curves of the animals in the several groups for the first 90 days of the experiment are shown in Figure I. The rate of growth of all these animals was considerably slower than that of animals fed the breeding diet; but by the end of 10 months the one-third ice cream group had reached the same weight as the breeding animals, namely, 375 to 400 gm. The animals fed ice cream alone were still gaining at that time and eventually attained the full mature weight for this strain of rats. The animals fed the basal diet

This shows four male rats, litter mates, each at 44 weeks of age, which had been fed respectively, from the time of weaning, on (a) the breeding diet, (b) the basal no ice cream diet described in Table I, (c) the one-third ice cream diet described in Table I, (d) standard commercial vanilla ice cream as the sole diet. The method of feeding diets (b) and (c) is stated in the accompanying article. Rat (a) weighed 375 gm., Rat (b) 205 gm., Rat (c) 400 gm., Rat (d) 300 gm., at the time the photographs were taken.

TABLE II

APPROXIMATE COMPOSITION OF BASAL AND ICE CREAM DIETS
(DRY MATTER BASIS)

	Protein Per Cent	Carbohydrate Per Cent	Fat Per Cent	Nutritive Ratio*
Basal	21.25	59.3	14.2	1 : 4.29
One-third ice cream	19.94	59.8	16.4	1 : 4.82
All ice cream	10.25	58.2	31.6	1 : 12.60

* Ratio between the energy supplied as protein and the total energy of the diet.

without ice cream ceased gaining when they attained one-half this weight, namely, about 200 gm.

Study of the individual growth records of the animals, which are omitted to save space, shows that at the end of the 90-day period none of the animals fed the basal, no ice cream diet, attained the weight of the poorest animal fed this diet mixed with one-third by weight of ice cream, although the mean consumption of total nutrients was the same. Likewise, only 1 animal in the basal group attained the weight of the poorest animal fed ice cream alone, each of the other 4 animals fed ice cream as the sole diet exceeding it by 15 to 30 gm.

A study has also been made of the efficiency with which the groups utilized their food for growth in terms of dry matter consumed for each gm. gained per 100 gm. body weight. The details are omitted for the sake of condensing this report. The mean values for the 90-day period were as follows: for the basal group, 8.74 gm.; for the one-third ice cream group, 6.04 gm.; for the all ice cream group, 5.44 gm.

The results of the experiment are believed to offer important evidence regarding the nutritive value of ice cream. The standard vanilla ice cream used was a valuable supplement to certain types of diet for growth. In addition, the same ice cream alone was capable of promoting growth at a moderate rate to produce mature animals of normal or nearly normal size and weight.

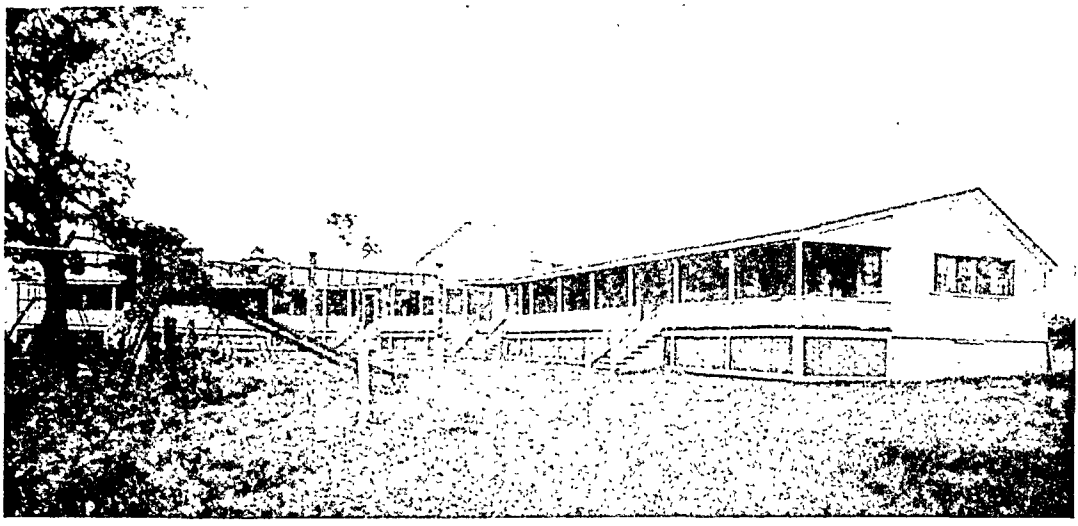

FIGURE I—Main Building, Lowell Summer Camp

Lowell Fights Undernourishment Among Its School Children*

JOHN J. McNAMARA, M. D.

Director of School Hygiene, Lowell, Mass.

LOWELL, Mass., with a school population of approximately 23,000, found itself compelled in the summer of 1928 to enter the good health market on a large scale. Its immediate purpose was the upbuilding of malnourished and underweight school children; its objective was the purchase of good health insurance for its future citizens.

An outdoor camp for 140 boys and girls and a health center with daily accommodation for 125 children were established. The money and effort expended were justified by the results.

For the last 4 years the annual examinations of the Massachusetts Ten Year Survey, conducted by the State Department of Public Health in conjunction with the Lowell Division of School Hygiene, have brought to light the fact that the number of Lowell children listed as the hilum tuberculous, the latent tuberculous, the suspects, and the contacts, formed surprisingly large groups. This hurt civic pride. A more startling fact, however, was revealed—that these groups, all of which came under the broad classification of the pretuberculous and underweight, made each year no worthwhile progress.

It was found that, while the examination of the children and the work of the teacher and school nurse, including advice to parents, were effective during the school year, during the summer months the results were largely lost. Though vacation should have been the pe-

* A resumé of an intensive summer campaign in health camp and health center.

riod of greatest gain, it was worse than wasted time. Knowing what these conditions meant for the future of the children and the community, and that there was no hope of passive acquisition of good health by these groups, the health department realized that if any material progress was to be made, the city must put forth its maximum of effort through the entire year, and that the break in the campaign for child health, from June until September, must be closed.

PLAN OF CAMPAIGN

In 1927 the city had established a municipal summer camp, and a health center had been sponsored by the Tuberculosis Council. They were valuable as a beginning, but left much to be desired. The obvious duty of the health authorities was to improve them, and make them coöperative and effective. The 1927 camp was for the day only. Transportation was furnished to and from a central meeting place in the city, but much of the good accomplished during the day was neutralized by the fatigue of the journey between home and camp. Moreover, there could be no supervision of hours of sleep, food, or hygienic habits, and there was an ever-present fear that some children might be exposed to contagion and on their return infect the camp.

In 1928, the ideal type of summer health camp was established. The so-called " Day and Night Camp," in which the children spend the entire 24 hours, was put into operation. It is, in several respects, ideally situated.

While the site is within the city limits, it has all the advantages of a country location. Although adequately isolated from dwellings and from contact with the more thickly populated city districts, it is easily accessible to parents, both by automobile and electric railway. Regulations, not too stringent, and easily enforced, prevent too many visitors at hours that might disrupt camp discipline and routine.

The grounds, some 10 acres, well grassed and drained, are on a fair elevation above the surrounding country. Northward is the valley of the Merrimac, and a clear, unobstructed view of the White Mountains in the distance. A grassy slope gives space for play, and a large oak makes a natural playground center with ample shade.

A wealth of recreational apparatus, practically all donated by the Lowell Gas Light Company, includes fifty swings, chutes, teeters, sand boxes for the very young, and athletic paraphernalia, basket balls, footballs, push-balls, volley-balls, a basket ball course, quoits and rainy-day and piazza games. A row of outside showers, with platform, made up for the lack of a wading pool, and were of practical use in the bathing of the children at the opening of the camp.

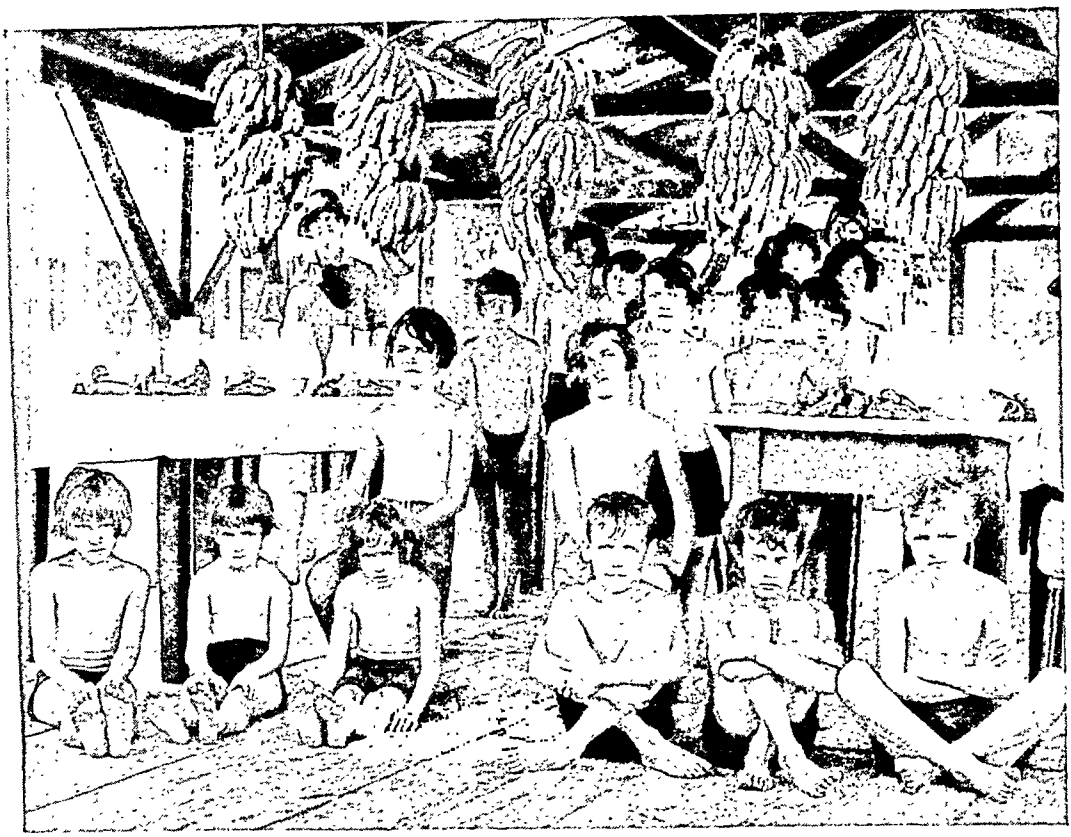

FIGURE II—Dining Pavilion, ready for milk and banana morning lunch

Permanent buildings capable of housing 125 to 140 children constitute the camp quarters. The main building has two wings, one used as sleeping quarters for the girls, and the other for the boys. Regulation iron hospital beds with mattresses, bed covering and linen, without pillows, are provided. A central administration building contains the director's office, nurses' quarters, and platform for scale and weight charts. There are two smaller buildings, one containing the kitchen and commissariat, with attached out-door, roofed dining pavilion, which accommodated the entire camp at meal time (Figure II), and the other a duplex toilet.

Sanitation of summer camps presents an important problem. The majority, because of their location, have no sewer connection, so that septic tanks and wells must be installed for disposal of excreta and waste. This was the method employed at the Lowell camp. Garbage and other waste were removed by health department employees every second day. An uncontaminated and plentiful water supply was available through connection with the city mains.

The personnel of the camp consisted of a director, 8 graduate nurses, 5 of whom had more than one year's experience in this type of work. Of the other 3, 1 was a school nurse who had had previous

contact with many of the children, and the other 2 were surgical nurses who spoke more than one language, mainly French. This was quite important in advising the parents of some of these children on their visits to camp. The value of a thoroughly trained and capable personnel cannot be emphasized too strongly.

The day shift comprised 3 nurses, a dietitian and her assistant, who were also nurses, and a physical instructor who acted as day custodian. The night shift was made up of 2, and for a time, 3 nurses, and a night custodian.

The camp was open practically 8 weeks, during July and August. Both boys and girls were cared for without any difficulty or undesirable incidents.

The selection of the children is of paramount importance and must be carefully made if the maximum value of such work is to be realized. Those selected should comprise the groups most in need of attention, either because of physical defects or a lack of health knowledge in their homes; they should be free from infectious diseases, and not recent contact with contagion.

The plan followed, recruited from the schools those listed in the Ten Year State Survey and by the school physicians and nurses as being among the hilum tuberculous, either active or latent, suspected or contacts with open cases, or those showing malnutrition as evi-

FIGURE IV—Morning Lunch Hour at Edson School Health Center

FIGURES V and VI—The Playground showing sand pile for younger children and vigorous activity which the children acquired as summer advanced

denced by being at least 10 per cent underweight. In addition some children recommended by private physicians and outside agencies were accepted. Before the opening of camp the candidates were given an examination to discover carriers of disease, or detect those from homes harboring contagious diseases. All suspicious throats were cultured. This also gave an opportunity to have carious teeth remedied before the opening of camp. During the school year a large percentage of the children recommended for the summer health camp were encouraged by the school nurses to have such foci as infected tonsils or teeth attended to in order that they might be eligible.

The average daily attendance at camp was 93—58 girls and 35 boys—augmented by 50 children during the last 2 weeks. These 50 had already received considerable preliminary training by continuous attendance for 6 weeks at the Edson School Summer Health Center, and were cases which, it was believed, would benefit to some extent even from the short time at the health camp.

DAILY SCHEDULE

7:00 A.M.	Out of bed. Roll call. Attention to personal hygiene, hands, face, teeth, under supervision.
7:20	Assembly for breakfast. Washing of personal dishes.
7:45	Arrangement of personal quarters, which included the making of beds by the older children. (Policing of the buildings, sleeping quarters and grounds performed by adult custodian.)
8:00	Recreation. Supervised play.
9:30	Heliotherapy. One-half hour maximum, lying prone on sheets in grassy play field in front of main building.
10:30	Mid-morning supplementary lunch. Milk and bananas, varied with crackers.
11:20	Postural exercises for selected groups.
11:40	Health talks in shade by nurses to their individual groups.
11:45	Preparation for dinner. Washing of hands. Assisting, and arranging noon meal.
12:00	Dinner.
1:00 P.M.	Rest period, in sleeping quarters, prone on bed.
3:00	Up and out in open.
3:30	Mid-afternoon lunch, milk and bananas. (Sometimes partly devoted to rehearsal of health plays for demonstration open to public.)
5:30	Assembly for supper.
6:15	Attention to personal eating utensils.
6:30	Play, campfire singing, games, story telling.
7:30	Chilly night, mug of hot cocoa.
8:00	Bed. Quiet.

This schedule was closely adhered to, with the exception of special occasions such as rainy days, when the rest period was prolonged.

The doctor, who was also Camp Director, made a daily visit to the camp, and frequently a second one in the evening. Daily medical inspection by the nurse in charge of each group was religiously carried out. Any children showing a rise in temperature or malaise were immediately quarantined, their personal effects segregated, all contact with the rest of the camp severed as far as possible, and measures against the possible spread of contagion, such as throat cultures, immediately taken.

MEANS TO HEALTH

Heliotherapy—The sun treatment was carried out in accordance with the most approved technic. The children, after becoming accustomed by increasing dosage to the direct rays of the sun, were gradually divested of clothing until only trunks were worn. This also had for its purpose what is almost as important as the sun bath, that is, the air-bath, to as much of the surface of the body as possible. In carrying out the sun treatment, careful watch was kept for the possibility of over-dosage and no untoward effects were noticed. A deep pigmentation of all those at camp was secured (Figure III).

Rest and Recreation—While recreation is of major importance in the summer health camp, these children, undernourished and underweight, need rest rather than strenuous exercise, because one of the important factors in bringing about this condition is over-fatigue, to which the child of school age is highly susceptible. The problem is to correct this over-fatigue and neutralize the toxic fatigue products. This can be done only by rest, and by this is meant complete relaxation, prone on bed or cot, as provided for in the daily schedule.

This chronic fatigue of the school child is usually due to lack of sleep, faulty food or health habits, and poor home hygiene, intensified often by too much outside work. It is also a fact that sometimes, because of the compulsory education law, the child is required to spend a large part of his waking day within school walls under more or less strict régime and at definite tasks, deprived of the fresh air and sunshine which he enjoyed during his preschool period. For this reason stress was placed on the length of the daily rest period.

Diet—Faulty diet plays a far greater part than was formerly supposed in bringing about not only malnutrition in children but also the degenerative diseases of adults. The ills due to a partially deficient diet, that is, one deficient in such mineral salts as calcium, the vitamins and the essential amino-acids, are of frequent occurrence.

FIGURE VII—Group which includes some of the most needy children taken at the end of the first 16 days. Children Nos. 2, 3, and 4 unfortunately left before the end of the camp session. They returned to school not improved.

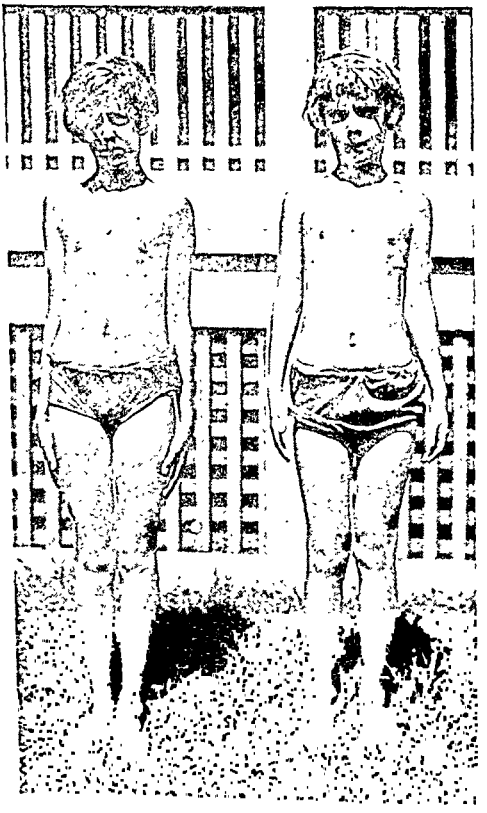

FIGURE VIII—Florence P. and Lucy N., the two children at the right in Figure VII at the close of camp. The marked improvement in posture and good effect of the sun treatment are readily seen. Their records are:

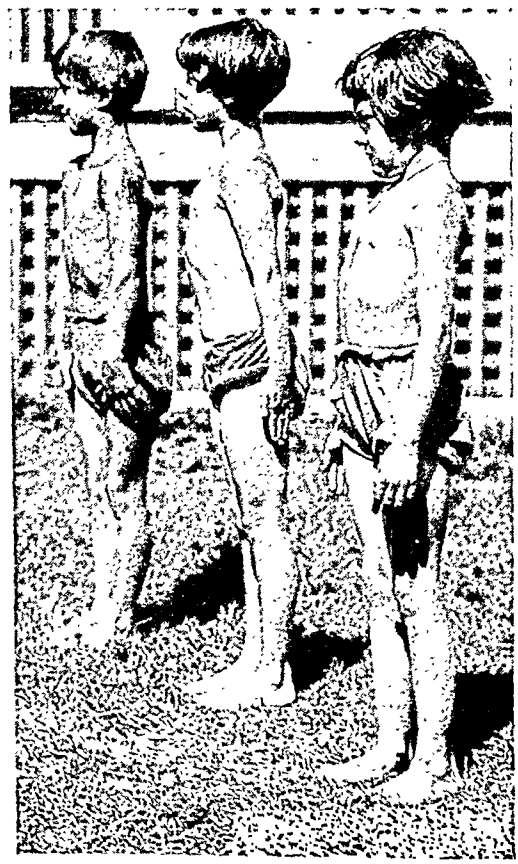

FIGURE X—Three who remained of group shown in Figure IX at the end of camp—Gladys K., Grace C., and Theresa B. While the posture may seem exaggerated, it shows an excellent appreciation of what constitutes correct posture, when on display.

Although the economic condition of the family may be a factor of considerable importance in bringing about such faulty food habits as result in malnutrition, nevertheless equally important is the lack of knowledge of what constitutes a correct and balanced diet. One result is that fickle food habits and unwarranted prejudices against certain essential foods are allowed to exist in children, and because of these, improper and inadequate diets for normal growth are found not only among the poor but even in the homes of the wealthy. As regards children, diet is in the main a matter of health education.

For these reasons careful attention was paid to this phase of the work. Not only was the daily menu compiled with great care, and attention to the requisites for nutrition and growth, but foods were chosen and menus arranged in such a manner that they could be provided and served in the homes to which these children would return. The purpose was to secure a correction of faulty food habits which might be continued after the children returned home.

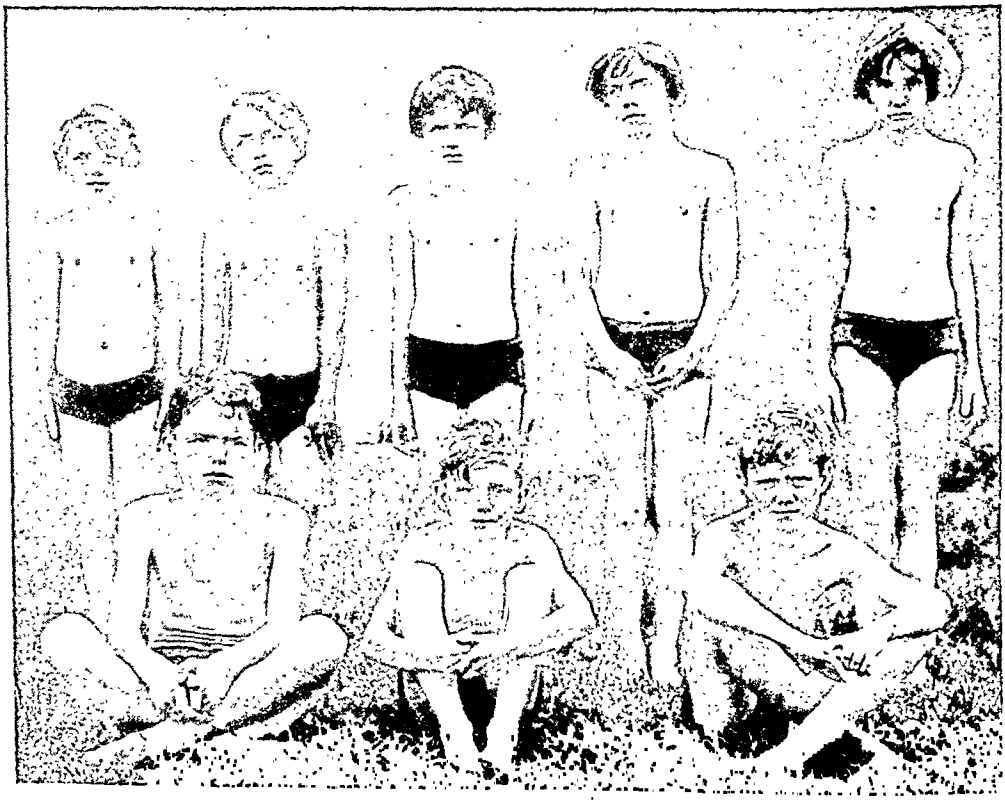

FIGURE XI—A typical group at the end of the first 16 days. Their records are:

NAME	AGE	HT.	WEIGHT BY WEEKS								
			1st	2d	3d	4th	5th	6th	7th	8th	Normal
Grace C.	9	47	44½	44½	45	47½	47½	49	49½	50	50
Gladys K.	10	47½	45½	47½	48¾	50	51½	52½	52¾	54	50

Eleanor W.	10	53¼	59½	63¼	64	66	66½	67½	68½	69½	68
Mildred M.	10	55	65½	64½	65	66	66	67½	66½	68¾	74
Stanley R.	12	59	80	80½	83	84	85	84½	86	86¾	89
George M.	8	50	54½	53¾	54¾	55¾	56½	56¼	56½	57	58
John O'C.	11	56¾	66½	68	69½	70	72	72	72	73	74

Since this phase of the work was essentially educational and its success depended upon continuity and perseverance of effort, certain follow-up work was necessary. The parents of these children were supplied with a mimeographed sheet containing a list of foods for breakfast, dinner, supper and the between-meal lunches, such as were given at camp, and which contained the necessary nutritive elements for child growth. This list is almost identical with that furnished by the State Department of Public Health.

Milk and bananas were chosen again this year as a supplementary lunch, not only because they furnish a complete food when used together, due to the fact that the ratio of carbohydrates and fats to proteins makes a well balanced diet, but also because the ripe banana is palatable and easily digested and assimilated. The combination also contains adequate amounts of vitamins A, B, and C, and the essential mineral salts. This choice of a milk and banana diet was due not only to its adequacy as a supplementary lunch for those children who were in special need of extra nourishment, but also to create a taste for a palatable food which might replace concentrated carbohydrates in the form of candy, or other sweets, between meals.

SOME HEALTH CAMP MENUS

Sunday

Breakfast	
Oranges	Sliced banana
Shredded wheat	Shredded wheat
Bread and butter	Pep
Milk	Bread and butter
	Milk
Dinner	
Chicken fricassee	Pot roast
Mashed potato	Baked potato
Green peas and onions	Peas
Milk and ice cream	Bread and butter
	Ice cream
Supper	
Chicken soup	Sandwiches
Baking powder biscuit	Canned pears or peaches
Banana and peach salad	Milk and cookies
Milk	

Friday

Breakfast	
Stewed prunes	Oranges
Sliced banana	Oatmeal
Pep	Bread and butter
Bread and butter	Milk
Milk	

Dinner	
Fish chowder	Fish chowder
Bread and butter	Green corn
Milk	Banana fritters
Stewed peaches	Peanut butter sandwiches
	Milk
Supper	
Tomato soup	Banana salad
Boiled rice	Bread and butter
Fruit salad	Milk
Bread and butter	Cream of pea soup
Milk	
Saturday	
Breakfast	
Oatmeal cereal	Dried peaches stewed
Sliced banana	Pep
Milk and top milk	Bread and butter
Bread and butter	Milk
Dinner	
Meat loaf	Pea soup
Mashed potato	Spinach
Brown gravy	Junket
Creamed carrots	Bread and butter
Banana and cream souffle	Milk
Bread and butter	
Milk	
Supper	
Baked beans	Scrambled eggs
Corn cake	Blueberry cakes
Milk	Bread and butter
Banana pudding	Milk and bananas

There were also mid-morning and mid-afternoon lunches of bananas and milk, sometimes varied with crackers. On chilly nights hot cocoa was served at 7:30. The children were not permitted to receive or accept gifts of food.

THE EDSON SCHOOL HEALTH CENTER

Inaugurated in 1927 and financed by the Lowell Tuberculosis Council as an experiment under the supervision of the Director of School Hygiene, the Health Center at the Edson School has developed into an important phase of municipal health activity. Its success warranted the appropriation of additional funds from the Council for the expansion of the work the following year.

A director without pay and a full-time nurse with salary, assisted by several volunteer workers, formed the personnel of this center, which was conducted 5 days a week with morning and afternoon

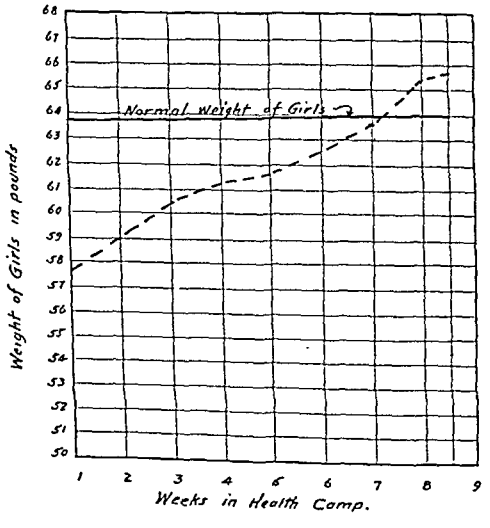
sessions, beginning at 9 and closing at 4:30. The average attendance was 125. Weighing and measuring, with physical examination of all children enrolled, was done and recorded on admission. The daily program included mid-morning and mid-afternoon lunches of bananas and milk, postural and corrective exercises, health education by daily talks, health plays and pageants and such activities as making health posters, illustrating nutritious foods by cut-outs from advertisements and pictures, with toothbrush drills and instruction in personal hygiene. In addition to this, on certain days each week, diphtheria prevention work was carried on by a volunteer corps of physicians assisted by health department nurses, through the administration of toxin-antitoxin to children of preschool and school age. Infant welfare work was carried on under the supervision of a pediatrician, and consultation with an eye, ear, nose and throat specialist was provided for all cases requiring it. The fact that on various occasions 40 or 50 parents visited the center in one day, and that many notes and inquiries were received concerning their children's health, showed that this clinic was making contact with groups heretofore difficult of approach, and that these groups were being enlisted under the banner of good health.

Supplementary lunches were provided, consisting of a ripe banana and a pint of milk morning and afternoon, varied occasionally by crackers and ice cream. The completeness and nutritive value of this food as a supplementary lunch to the ordinary meals was evidenced by a gain in weight of from ¾ to 2¼ pounds during the period that the health center functioned. (Figure IV shows the morning lunch.)

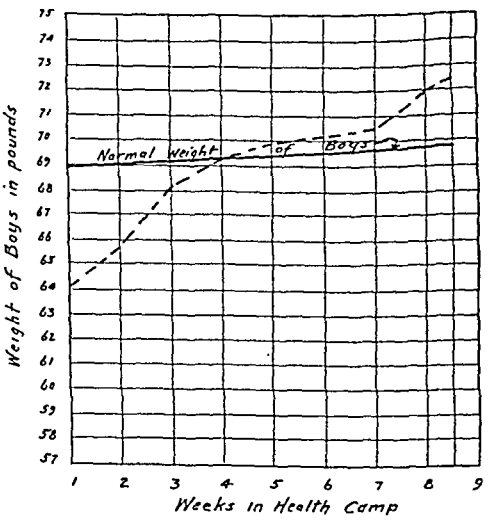
Amazingly good discipline was evidenced at both health center and camp. In the few instances of infractions of camp rules, just penalties were inflicted immediately, and took the form of increased rest periods, even up to an entire 24 hours in bed.

These were few but noteworthy. We regret that several of our most needy cases stayed but a very short time, due in part to inopportune visits from parents either alone or accompanied by former playmates of the children, or members of the same family of about the same age, during the first week of camp. These visits, coming at the only time when the children felt any homesickness, caused a few to return prematurely to their homes. Others, because of ignorance on the part of the parents, were taken from camp on refusal of the authorities to allow the children or visitors to go and come when they pleased. A signed agreement from these parents guaranteeing a stay of 8 weeks would have eliminated these difficulties.

Finances for this type of camp were voted by the health department, due in no small part to the popular demand created by the Lowell press in timely publicity and endorsement of the value of this work, and through the sponsorship of certain agencies actively concerned with community health and civic welfare, such as the Lowell Tuberculosis Council, the Lowell Chamber of Commerce, and many of the city officials.



The success of the camp was due to a great extent to the men forming the Lowell Board of Health. Awake to the great possibilities of this work in improving the health of the children, they rendered every assistance possible to the Director of School Hygiene.



RESUMÉ OF WORK ACCOMPLISHED

The beneficial results of the summer session of the Lowell Health Camp were threefold.

1. Improvement in the physical condition of the children was evidenced by an average gain in weight of over 7 pounds; a bright and happy appearance as contrasted with an apathetic and listless attitude on entrance; vigorous activity; improved muscular tone; a skin healthy in appearance and firm to the touch, with a deep pigmentation of practically the entire body; better posture, with a lessening of the fatigue posture characterized by "winged" shoulder blades, curved back and marked ptosis of abdomen common to practically all at the time of entrance; and the ability and willingness to eat the simple, correct and nourishing foods which comprised the camp menu.

COMPOSITE WEIGHT CHARTS

2. The acquisition of considerable health education was shown by a voluntary adherence to the precepts of personal hygiene, such as cleanliness of face, hands and body, improved oral hygiene, attention to appearance, and care of personal property. In addition, every child had a positive knowledge of what constituted a correct diet and an appreciation of the value of fresh air, sunshine and sufficient rest.

3. There was inculcated a very definite respect for constituted authority and for the rights and privileges of the other members of the camp, which, together with a healthy body and a sound mind, are the qualities which go to make a desirable and welcome future citizen.

VALUE AS A HEALTH DEMONSTRATION

For the success of any program intended for the betterment of child health the coöperation of the public is necessary, and to secure this an educational health crusade must be promulgated. In gaining this appreciation and coöperation, such demonstrations as summer health camps and summer health centers are very efficient agents, the more so because, generally speaking, health departments are handicapped by the failure of the adult population to recognize in their work something of immediate and tangible value to themselves. The success of these health programs depends to a great extent on the amount of health education " sold " to the public. It is not too far-fetched to say that preventive medicine as a whole is three-fourths educational.

No better form of advertising for any city is possible than the knowledge that the health of its children—the future citizens—is receiving the consideration and attention which it should. Disraeli once said: " Public health is the foundation on which rests the happiness of the people and the welfare of the state." It is to the credit of the city of Lowell that it maintains for its undernourished children perhaps the only, and certainly one of the very few, municipally financed summer health camps in the United States.

The Outlook for Mortality Statistics by Occupation*

LEON E. TRUESDELL, PH.D.
Chief Statistician for Population, Bureau of the Census, Washington, D. C.

OCCUPATION is one of the factors which determine the death rate; a double factor, made up of the direct hazards, which affect only the worker, and of the attendant living conditions, which affect both the worker and his family. The presentation of adequate statistics of deaths classified according to occupation ought, therefore, to form a part of any comprehensive program for vital statistics. It remains to determine at just what point this feature should be taken up, for there are many other items, some of them of much more immediate importance, and nearly all of them easier of accomplishment. The logical procedure would seem to be to let the matter of occupational classification wait until the more urgent features had been established, or were well on the way toward a satisfactory status.

The census reports of 1890 and 1900 gave considerable space to the classification of deaths, not only by occupation, but by occupation with age and cause of death, but the mortality statistics up to this time were very imperfect. The reporting of deaths by the census enumerators had failed to obtain even the total number. The transcription of state records in a limited registration area had been used to supplement the enumerators' work in 1880 and 1890, but the idea of extending this method and making it the basis for annual statistics of mortality was only taking definite form in 1900.

For the 25 years following 1900 the main effort of those in charge of collecting vital statistics for the United States was directed to the extension of the registration area and the improvement of the returns both in quality and in completeness. In 1915 the compilation of birth statistics was begun and a birth registration area established. This met a need far more urgent than any amplification or further classification of the death statistics.

Gradually, states have been added to the registration areas for deaths and births, 44 being now included, with about 95 per cent of

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

our population; and for most of this territory the number and causes of deaths are satisfactorily reported. We may now divert a bit of our time to classifying the death returns by occupation.

The first thing is to find out what materials are at hand and to what extent they are in shape to meet the new requirements. Tabulations of deaths classified by occupation have been made for some of the years between 1900 and the present. Tables of deaths classified by occupation were published in the reports for 1908 and 1909, though without any rates, since parallel figures for population were not available for years so long after the census year. In 1910 the tabulation was again made and rates were computed; but the results showed so much inconsistency and so many relations that did not seem reasonable, that the tables were never published. The experiment was repeated in 1920, with results still unsatisfactory. These attempts establish the fact that the disinclination of the U. S. Bureau of the Census to publish occupational mortality figures under present conditions is based on a realization of the imperfections in the material rather than on inertia or lack of appreciation of the importance of the subject.

For the computation of death rates for occupational groups, two kinds of material are needed: deaths classified according to occupation, and population data classified in the same way. The occupational classification of the two factors must be made, so far as possible, on a uniform basis. Any adequate interpretation of the death rates when computed requires also some age classification; for in many cases a high death rate for a given occupation taken as a whole will appear upon analysis to be primarily the result of the high average age of the persons engaged, or *vice versa*. The death rate for farm operators, for example, will certainly be far higher than that for farm laborers, because the latter are mainly young men. Some classification by cause of death will also be needed, since the influence of occupation on mortality frequently takes the form of an increased (or decreased) likelihood of death from certain specific diseases.

One of the principal difficulties in compiling occupational mortality statistics is that of securing accurate returns on the death certificates. A recent examination of more than 1,500 certificates, selected from representative areas, showed that only about 70 per cent contained occupation returns sufficiently complete for a satisfactory classification. Among the inadequate returns the most common defect was the entry of some indefinite term, such as " clerk " or " laborer," without any statement as to the industry or business. While information as to the industry is not absolutely required in all cases, it is essen-

tial to the classification of laborers and some other groups of workers; and there seems to be no way of insuring its presence when needed, except to insist on having an answer to the question covering this point on all certificates.

The occupation returns on the general census schedules are not all complete and satisfactory, but the proportion of unsatisfactory ones which have to be given an arbitrary classification or thrown into some residuary group is much less than 30 per cent. Entries in other parts of the schedule, and for other members of the family or residents of the locality, often prove of material assistance in classification, where this is made for the whole population. Such assistance is entirely wanting, of course, in the isolated cases represented by the death certificates.

The occupation returns on the death certificates ought to be at least as accurate as those made by the enumerators on the census schedules. In both cases the information is usually obtained from members of the family. The undertaker, physician, or other informant is probably more intelligent and more accurate than the average census enumerator; further, he is recording information with regard to occupations almost daily and not, as in the case of an enumerator, for a brief period once in 10 years.

The two primary occupation questions on the standard death certificate are similar in a general way to the corresponding ones on the population schedule, but there are minor differences in form; and these may be in part responsible for the less satisfactory returns on the death certificate. The occupation questions on the death certificate are as follows:

8. OCCUPATION OF DECEASED
(*a*) Trade, profession, or particular kind of work .....
(*b*) General nature of industry, business, or establishment in which employed (or employer) .....
(*c*) Name of employer .....

For the sake of making the death certificate uniform with the population schedule it is proposed to revise this section to read as shown on the next page—substituting two new questions (numbered 10 and 11) for the "Name of employer," which seems to serve no particularly useful purpose:

OCCUPATION	8. Trade, profession, or particular kind of work done, as *spinner, sawyer, bookkeeper,* etc. ..... 9. Industry or business in which work was done, as *silk mill, sawmill, bank,* etc. ..... 10. Date deceased last worked at this occupation (month and year) ..... 11. Total time (years) spent in this occupation .....

It is believed that the listing of specific examples of the kind of entries desired under both trade and industry will make clear the requirements for these two questions in many of the cases where the distinction has not been clear heretofore, and that the importance of answering both will be more evident if they are given independent numbers, " 8 " and " 9," in place of being presented as subdivisions " (a) " and " (b) " under a general designation.

More serious than these minor differences in the form of the inquiry on the face of the standard death certificate would seem to be the statement in the instructions on the back: " For many occupations a single word or term on the first line will be sufficient." This is followed by an explanation of the fact that in other cases entries are required both on the first line (trade or specific occupation) and on the second line (industry); and if the instructions, as they stand, were followed absolutely, the results would be satisfactory. The inevitable psychological effect, however, of the statement quoted, has been the return of numerous certificates with entries on the first line only, even though the cases were plainly included under specifications printed later in the paragraph and definitely calling for a second entry. It is believed, therefore, that a radical revision of the instructions, putting stress at the very beginning on the necessity for reporting both specific occupation and industry, coupled with the proposed changes in the form of the questions, will result in a great improvement in the returns; and that if this is accompanied by special emphasis on the necessity for making complete and accurate returns of occupations, the data will soon be in satisfactory form.

The new section proposed, including questions 10 and 11, need occupy no more space than does the occupation section on the present standard form. Question 10 is added as a basis for separating retired persons from those actively engaged in the occupation returned up to the time of death or the beginning of the illness which resulted in death. It is believed that a definite question like this will give more satisfactory results than any provision for returning persons as " re-

tired." Question 11 is designed to give some information with regard to change of occupation, which is probably more frequent among American workers than among those in any other country.

Since it will doubtless be expedient to start the publication of occupational mortality statistics in a relatively small way, rather than to undertake to cover the whole field in the first year, it has been suggested that for a time the presentation be limited to statistics for males; and even to those for males 20 to 64 years of age.* The connection between occupation and mortality is far more direct and important with males than with females, since 92.6 per cent of the male population 16 years of age and over are gainfully employed, as compared with 23.9 per cent of females. The connection is doubtless far closer with males within the suggested age limits than with either those under 20 years or over 64; for the former have had only a brief experience in any occupation and the latter are approaching that period in life when death is imminent, no matter what the occupation may be. Another factor which is rendered less serious by the omission of persons over 64, is retirement. Many persons dying in old age will have retired from gainful occupation some years prior to their death, but frequently, in spite of all precautions, the earlier occupation will be reported on the death certificate with no indication of the retirement.

It is proposed to base the occupational death rates on the number of gainfully employed persons regularly returned in the census of population, which does not include retired persons. Presumably, these should be excluded also from the number of deaths used in computing the rates, though this does not necessarily follow. It would seem illogical to include retired persons in the deaths and not in the basic population; but in practice this combination might yield the more significant results. It would take account of one additional factor, the variation in the relative number of deaths from retired status in the various occupations (and from the various causes of death); and except for this the rates would run parallel with those based on the complete elimination of all "retired" cases, only on a uniformly higher level.

An alternative plan which has been seriously considered is that followed in the English census, where the attempt is made to include all retired persons,† classified according to the occupation followed prior to retirement, both in the number of deaths and in the population

* The statistics presented in the English report on occupational mortality for 1921 relate mainly to the age group 20 to 65.

† The basic population group under consideration in most of the tables in the English report on occupational mortality is "All occupied and retired civilian males."

groups. This method would perhaps be the ideal one if it were possible to obtain the required information with accuracy and facility. Even in England, where the institution of vital statistics has been established for a much longer period than in the United States, it is admitted that the population statistics for a given occupation fall considerably short of including all retired persons who had followed that occupation.

One of the important considerations in favor of basing occupational death rates on data for the gainfully employed population, exclusive of retired persons, has been that of expediency. The process of classifying the returns of the decennial population census according to occupation is a task far greater than any other one part of the work leading to the publication of occupational mortality statistics. From the beginning, the practice has been to include in the various occupational classifications only those persons actively engaged in the occupation at the time of the census, or temporarily idle on account of failure to find employment. To expand this group to include both the gainfully employed and the retired population would result in some confusion and in somewhat less accurate classifications, in addition to making a material increase in the work.

The requirements of expediency were supported, however, by a feeling on the part of some members of the staff of the Bureau of the Census that death rates based on fairly good data excluding retired persons would be at least as significant as those which might be based on imperfect returns for all persons who had pursued the various occupations, including those retired; and in particular, that the relation between the rates for one occupation and another would be typical and significant.*

Further, in spite of the English precedent, there is ground on which we might question the validity of including both retired and occupied in one total and treating the combination as a unit in computing death rates. In many occupations the death hazard of those at work is decidedly greater than that of those who have retired for reasons other than disability resulting from the occupation. This is especially true in occupations where the likelihood of accident or the results of exposure are important factors, as, for example, coal miners or telephone line men. Retirement on account of disability would usually connote an increased likelihood of death. In either case there is reason for insisting that the two groups should not be mixed—that if statistics

* These relations would not be identical, of course, because of the variation in the relative numbers of persons retired from the various occupations; but one might contend that while two curves representing the two sets of rates for a series of occupations, one based on the occupied population and one on "occupied plus retired," would not run absolutely parallel, they would correspond rather closely in their major ups and downs.

are to be presented for the retired, they should be kept entirely separate from those for persons actively employed. Here is a field in which we ought at least to do some preliminary experimental work, so as to know positively what will be the effect of combining these two elements.

Something like this is what we have in mind for the immediate future program in the Bureau of the Census. It is proposed to make a careful study of the extent to which occupations are normally returned for retired decedents, which will be indicated by the replies to question 10 (date of last active employment) in the revised form of the death certificate. It is proposed also to make a study, on the basis of the replies to question 11 (total time spent in this occupation), of the extent to which men change their occupation, giving especial attention to the changes taking place after middle life, which may prove to be a more serious disturbing factor in American statistics of occupational mortality than the matter of retirement. On the basis of definite information secured from these studies, it will be possible, as the work develops, to make any changes in the general plan that may seem profitable.

One further limitation imposed by the dictates of expediency will restrict the value of the occupational mortality statistics which can be compiled in the immediate future. Many of the occupation classifications now employed represent so large a group of specific occupations, including persons working under widely different conditions, that they will not bring out in any positive fashion the effects of occupational hazard. In fact, it seems likely that for the first few years the really significant occupational mortality figures will be the rates for a relatively small number of occupational groups, including those in which the conditions of employment are relatively uniform and those which by reason of a definite and universally used occupation designation will be most accurately returned both on the population schedules and on the death certificates. The first stages of improvement will come with the gradual increase in the accuracy of the occupation returns. Later, when the social value of these figures has been demonstrated, it may be possible (and justifiable, in spite of the expense) to make extensive subdivisions of the present occupation groups to segregate those classes subject to particular occupational hazards. The major consideration at the present time, however, would seem to be the formulation of a program which is simple enough to be immediately practicable, and which will at the same time provide enough detail to be of positive and appreciable value.

A Swan Song in Public Health Work

EMERY R. HAYHURST, M. D., FELLOW A. P. H. A.

Ohio State University, Columbus, O.

IN THE midst of the controversies of the day as to how much we are really gaining or losing in the fight against disease and the raising of the level of life for mankind, it is a bit of relish indeed to pick up the report of a man retiring from the active field of public health work, who was in at the beginning of the century, who kept faithful records through the intervening years, and in a simple short story now publishes the results.

In February, 1901, Dr. Richard King Brown took office as the first full-time Medical Officer of Health of the Borough of Bermondsey, England, a populous section of London, S. E., and his *Annual Report of 1927* to the Mayor, Aldermen, and Councillors closes a long and noteworthy official career.

Many changes have occurred in public health during this first quarter of the century, and Dr. Brown says that the advances have not occurred gradually, but by leaps at more or less well defined periods. The changes have been partly local, that is, confined to the borough itself, and also partly local expressions of national changes. A single table in the forepart of his report speaks volumes, and shows the important changes year by year from 1901 to 1927 inclusive.

Beginning in 1901 with 130,760, the borough, in 1927, had a population estimated at 121,000, composed of 29,284 families located in 18,034 houses. The reduction has been very largely due to the pulling down of certain buildings for improvements, but also to the replacement of houses by factories and the reduction in the birth rate, as well as to migrations to the suburbs.

The death rate has been reduced not quite by half, that is, from 20.8 to 12.9, and, while annual fluctuations have been marked, Dr. Brown feels quite safe in saying that the reduction is likely to be permanent. A more remarkable reduction is that of the birth rate, that is, from 34.2 per 1,000 in 1901 to 18.5 in 1927, and this also seems to be of permanent character, and by no means an unmitigated evil, because it has been paralleled with a marked reduction of infant deaths, and there is surely a correlation between the two.

The reduction in the infant mortality rate is considered to be

due chiefly to the reduction in the size of families. The very large families—10 to 15 and upwards—were not able to take good care of infants and the loss of a few was not looked upon as very serious. Families were huddled together in overcrowded houses, the result being that infectious diseases, particularly pneumonia and bronchitis, played havoc among the children. Another cause for reduction in the rate is probably the education of the mothers in taking care of infants, and this must be partly due to the rise of general education, and the special education undertaken by the municipal authorities and voluntary bodies under the stimulus of the Maternity and Child Welfare Acts. Other contributory causes, no doubt, are the rise in the rate of wages and the cheapening of food, but Dr. Brown thinks the first two causes mentioned have played a great part.

Very satisfactory reduction in tuberculosis, enteric fever, and smallpox is noticeable, but there seems to be no very material change in the prevalence of scarlet fever and diphtheria; in fact, they are inclined to increase, and the only thing that can be said of scarlet fever is that the form of the disease is much milder in this later day. We note no comment in Dr. Brown's report regarding immunization against scarlet fever or diphtheria; so in all probability his statements refer more or less to the natural status of these diseases left to the usual quarantine procedures. There was a serious outbreak of smallpox of 331 cases in 1901–1902, but since 1904 there have been altogether only 6 cases of this disease. Puerperal fever still remains a serious problem, and no doubt in the near future some method of reducing the mortality will be found.

Most interesting changes have taken place in the general condition of the inhabitants, especially the working classes, who now dress better and much more sensibly, and possess much greater general knowledge, especially in relation to health. There has been great improvement likewise in the cleanliness, ventilation, and general appearance of the homes.

Greatly increased sobriety prevails. There is no question that drinking is much less prevalent than it was 27 years ago. The appearance of a drunken man in the streets, which was by no means uncommon in 1901, was extremely rare in 1927. Here again, education has probably played the chief part, says Dr. Brown, though, no doubt, high taxation of alcohol, as well as the restriction of the list of sale, has had something to do with it. This condition should be looked upon as a great gain, and it can confidently be assumed that the population will be much more sober in the future, brought about, not by oppressive legislation, but by increased education.

The health department itself has been subject to important changes, from that of a part-time medical officer in charge, with a few assistants, to a department which is now composed, in addition to the Chief Medical Officer, of 7 sanitary inspectors; 7 district inspectors; 2 tuberculosis officers, assisted by 4 nurses and a caretaker; 2 medical officers for maternity and child welfare, assisted by 8 women health visitors; 1 full-time and 1 part-time dental surgeon, with 2 dental nurses and 3 prosthetic assistants; a convalescent home with a matron and nurse (with the admission of 255 women, 126 babies and 119 toddlers during the year); a public analyst; and a clerical staff consisting of 12 persons, in addition to a mortuary keeper, and a foreman disinfector. Some idea of the nature of the work of the department at present can be gained by a glance at this list of officers.

An interesting sideline has been a liaison with Dr. A. Rollier of heliotherapy fame, Leysin, Switzerland, by which not only were 6 beds for patients from the London Borough reserved there, and more or less completely occupied since July, 1924, but a solarium was also opened in the district itself in July, 1926, which proved of great benefit. Practically all of the patients are recommended for treatment in the solarium by the doctors from the various maternity and child welfare centers and from the tuberculosis dispensaries or hospitals. It is the first municipal solarium on any considerable scale in England, and has had visitors from all parts of the world. The attendance in 1927 totalled 24,322, examinations 2,226, new patients 456, maternity and child welfare patients 265, tuberculosis patients 107, and other classes of treatment 322. On the whole, cases of rickets and malnutrition have done well and shown very rapid improvement. The same may be said of antenatal cases, and the majority of these have returned after confinement for further treatments. There is little doubt about the value of light treatment in surgical tuberculosis if given cautiously, and none of the 18 cases of pulmonary tuberculosis treated has so far been injuriously affected, and in one or two cases the results have been gratifying.

Not an inconsiderable part of the detail work of the Health Office has had to do with the inspections of factories and workshops. During 1927, 630 such inspections were made in the district. Scores of defects in cleanliness, ventilation, sanitary accommodations, and other nuisances were found and remedied in the 413 workshops on the registry. Certain matters were referred to H. M. Inspectors of Factories and others were administered by the department itself. Observations upon smoke nuisances have formed a part of the health department's routine, with the filing of notices and summonses.

Among the later activities of the department has been health education, or propaganda, which was set up on a more extensive scale in July, 1924. The department has published a series of articles; given lectures in the open air, at schools and clubs; and, after investigating the films on the market, decided to make its own, which has proved very successful. The war opened the eyes of the nation to the value of public health work, as is shown by the tremendous and unremitting interest which the council now takes in the department.

It must surely be a satisfaction to the venerable Dr. Brown to submit an annual report of this nature as his epilogue, while health officials in America may well take heart and profit from his endeavors.

The gains described by Dr. Brown, sometimes enormous, can hardly be attributed to other than society's organized battles against disease and ignorance. Even the geneticists must acknowledge that no amount of natural selection or inheritance could bring about in one generation results such as these. We are pleased to note that even in a crowded section of London, and despite the vicissitudes of wars, unemployment, and traditional hindrances, none of which we can fully grasp in this country, even better progress has resulted than with us, and a part of it with less stringent laws. Detailed regulations are a characteristic of British procedures. There is, however, this marked difference in the British and the American methods—the former grasps the economic issue early and sees the wisdom of sidestepping politics in fundamental matters and of giving sound support in men and money to the projects which present themselves.

Leprosy Treatment

THE treatment of leprosy at the National Leprosarium, Carville, La., is progressing favorably. What is ordinarily considered cure, though not so designated by the authorities, is an accomplished fact.

In the seven years since federal acquisition, 31 patients have been discharged from the hospital—3 as not having been lepers and 28 paroled as "leprosy arrested and no longer a menace to public health." Of these 28, 1 (or 3.6 per cent) suffered a relapse and was readmitted, 4 having died (2 were examined at autopsy without tangible evidence of leprosy being found), and 23 are living and well and report periodically for reëxamination. The average age at which parole began was 44.8 years, and the average period of hospitalization was 6.4 years.

Of 718 hospitalized during 34 years, 215 were foreigners, 503 natives of the United States—418 came from Louisiana, and the others from California, New York, Texas and Florida.

Lead Poisoning in the United States*

TO YOUR committee it appeared desirable that its work be divided into two parts. The first is given over to an uncritical compilation of publications related to lead poisoning not limited to this country, since foreign achievements inevitably influence the incidence and control of lead poisoning in this country.

The second part is devoted to a number of unrelated items pertinent to the status of lead poisoning in this country during but not confined to the specified period.

THE DIMINUTION IN THE INCIDENCE OF LEAD POISONING

Several publications have commented upon the diminishing numbers of lead poisoning cases and deaths. Any proper estimate must recognize that the production and use of lead in this country is now more than double that for 1900, and the first decade of the century. In 1900 the production was 270,824 short tons; in 1927, 687,273; and 1926, 708,147 short tons. In view of this marked increase in lead manufacture and use it might be inferred that a correspondingly large number of workmen are exposed. This probably is not true for trades well established about 1900, and continuing to the present. In 1899, 8,751 workers produced 208,466 tons of lead, while in 1925, 6,115 produced 651,000 tons. In 1900 there were 277,541 building trade painters, in 1910, 273,441, and in 1920, only 248,897 (Census Report). Comparable figures for the period covered in this report are not available. From the figures it is reasonable to assert that the actual number of workmen exposed to lead may be less than in either 1900 or 1910, notwithstanding the extension of newer trades, such as automobile storage battery manufacture.

It is upon this type of information, rather than upon any precise and comprehensive records, that claims as to decrease in the number of cases must be predicated. In addition, your committee accepts as contributory factors in the assumed lowered incidence of severe or fatal lead poisoning:

1. Frequent physical examinations of lead workers required by law in some states, and voluntarily introduced by some industries and labor organizations

* Abridged report of the Committee on Lead Poisoning (year ending June 30, 1928), presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

2. The recognition of lead poisoning in its early stages, which permits of treatment under ambulatory conditions, without loss of time from employment

3. The development of improved types of machinery, such as the enclosed electrically heated Mergenthaler linotype

4. The improvement in substitute paint bases, such as lithopone, until they are essentially as acceptable as white lead or other lead compounds

5. Generally better working conditions throughout the lead using industries

6. Shortened exposure periods through shortened work periods

This committee believes that the incidence of lead poisoning is far higher than is commonly believed or reported to state departments of health, compensation boards, etc. One state official expresses the opinion that his records represent not more than 5 per cent of the cases. Of 208 cases reported during the past two years, the majority originated in a few plants which had become much interested in plumbism; only 2 cases among painters were included. In another state, in approximately the same period of time, 54 cases occurred among painters and decorators, notwithstanding the fact that fewer persons were engaged as painters. This assumption of a greater incidence of lead poisoning than reported is further borne out by the special physical examinations of those engaged in hazardous lead work. Such investigations frequently reveal large numbers of mild or obscure cases which otherwise probably would never have been diagnosed. In one plant in Nashville, Leathers and Morgan found that 26 of 39 workers in an enameling plant showed lead poisoning.

This committee believes that the intake of lead in small quantities is widespread among the workers of many lead using industries. This may be followed at no subsequent time by the clinical condition known as lead poisoning. There are some reasons to believe that remote degenerative diseases may be influenced as to time of development and severity by lead in amounts below the threshold of clinical response. In the absence of exact data, we regard the control of limited lead hazards as desirable.

The incidence of lead poisoning has not been so lowered that any negligence on the part of the industrial hygienist is warranted.

INDUSTRIAL COMPENSATION

Only 11 states provide for compensation and medical relief for those exhibiting lead poisoning: New York, Maryland, Illinois, Wisconsin, North Dakota, New Jersey, Massachusetts, Connecticut, Minnesota, Ohio and California.

With few exceptions all states have provided compensation and medical relief for industrial injuries. Although the disability from lead poisoning may be as genuine as that from the more obvious injury,

this, with other occupational diseases, leads to neither compensation nor medical care through direct provision, except in the above mentioned states. In a few states not providing coverage for occupational diseases, lead poisoning has from time to time been held to be an accident, and therefore compensable.

This committee maintains that if the practice of providing compensation and medical relief for industrial injuries is sound, similar measures should be provided for lead poisoning, and for all other characteristic occupational diseases.

SHORTENED WORK PERIODS AND PREFERRED REMUNERATION

It has appeared that some units of organized labor are disposed to base claims for shorter hours and increased remuneration upon the hazards of work. It is argued that if trade processes entail dangers to exposed workmen, the risk will be diminished if a lessened exposure, such as a 5-day week, takes place. Further, since the employer is responsible for, and a shorter work period is necessitated by, the hazard, payment should be made on the basis of a 6-day week.

Where it can be shown that lead, or other occupational exposure, is a factor in shortening the life expectancy of workers, and if the hazards cannot be eliminated, this committee agrees that such unfavorable conditions constitute a just basis for remuneration in excess of that provided for work in which comparable hazards do not exist, and for shortened work periods, if it may be established that these diminish the probability of the characteristic occupational disease or diseases. It is, however, not in sympathy with the use of health hazards as a basis for complaint merely that the economic status may be bettered. The danger is that no demand or effort will be made to eradicate the hazards—rather they will be cherished as leverage for continued economic pressure.

PRESENCE OF LEAD IN EXCRETA OF APPARENTLY NORMAL PERSONS

Extensive work has been directed to the measurement of lead in the urine and feces of persons not known to have been exposed to lead. It appears that traces of lead may regularly be detected in the urine or feces, or both, from apparently normal persons. The source is unknown—it may include food, food containers, lead foil wrappers, cooking utensils, lead flakes from paints.

In view of such findings, this committee suggests that no great diagnostic significance be attached to the detection of lead in urine in qualitative amounts only. Urinalyses appear to be of value in

the diagnosis of lead poisoning only when quantitative, and the quantity found should be in excess of traces common to practically all apparently normal persons.

The Scientific American has pointed out a new hazard in the substitution of lead oxide or lead phosphate for tin in the weighting of silks. It is not yet established that this new hazard extends beyond the textile worker, to the wearers of leaded silk garments, and laundry workers.

Uttal has traced some poisoning to snuff, through the use of lead chromate for coloring, or lead bearing metal foil for wrapping.

McCord has observed lead poisoning in forging machine workers. In punching holes in solid forged rods, the area is coated with white lead. As the hole is punched, hot lead vapor is formed which is inspired by the machine tenders.

Lead poisoning continues to be this country's outstanding occupational disease hazard.

CAREY P. MCCORD, *Chairman*
DOROTHY K. MINSTER
ROBERT KEHOE *

* Dr. Kehoe, owing to his absence from the country, has not seen this report in its present form.

The Health of German Women in Industry

AT the recent annual meeting of the Society of Industrial Hygiene of Germany, it was stated that 40 per cent of the 6 million women gainfully employed in Germany are married. The combined demands of employment, housework, and the care of the children were considered by some of the speakers as having a harmful effect on the women's health. According to statistics of the sick insurance funds of Germany, membership in which is compulsory for all employed women and girls, the sick rate of their women members is on the average 22.5 per cent higher than that of the men members, and the duration of illness is 3 times as long. Particularly unfavorable is the situation in the textile industry. The incidence of illness among gainfully employed women is from 5 to 8 times as great as among those who are not employed. Particularly frequent are diseases of the organs playing an important part in reproduction.

Because of the above facts, the speakers emphasized in the first place the need of more effective legislative protection of employed young people and women, many of whom are mothers of little children, and secondly the need of welfare work with expectant mothers, infants and older children.—*Jugend und Beruf*, Berlin, Jan., 1929, p. 14.

Status of Silicosis*

SILICOSIS, fibrosis of the lungs due to breathing air contaminated by siliceous dust, is found in many industries and in many states. While it has been known for many years by physicians closely associated with the industries causing the disease, the first systematic study in the United States was made in 1914 and 1915 by Lanza and Higgins [1] among the lead and zinc miners of the Joplin, Mo., district. Lanza examined 720 miners, making a limited number of X-ray negatives of the chest. Of those examined, 179 were free of lung disease; 69 were diagnosed as having more fibrosis of the lungs than normal; 330 had silicosis in some stage; 105 had silicosis and tuberculosis; and 39 had tuberculosis uncomplicated.

Harrington and Lanza [2] made a similar study in Butte, Mont. Of 1,018 miners examined, 432 showed definite signs of injury to the lungs due to dust; 194 had early silicosis and 7 were also tuberculous; 1,128 had moderately advanced or second stage silicosis, 8 of whom were also tuberculous; 110 had advanced or third stage silicosis, of whom 48 were tuberculous.

In 1919, the U. S. Public Health Service published [3] a report on the dust conditions in sand blasting and the efficiency of certain protective devices. The respirator tested was of the ordinary muzzle type with a rubber body fitting over the mouth and nose, and an air filter of two layers of 75-mesh muslin and a piece of sponge about $2\frac{1}{2}'' \times 3'' \times 1''$. The average number of dust particles less than $10 \times 20\ \mu$ when aspirated through this respirator was reduced from 49,400,000 to 4,549,000 per cu. ft. This reduction, while great, was not considered adequate. An aproned helmet, made of cloth covered cardboard having a $3'' \times 4\frac{1}{2}''$ window, was tested with a respirator, and with positive pressure both with and without the respirator. The helmet alone, with positive pressure sufficient to produce a current between 2 and 3 cu. ft. per minute, reduced the number of particles from many millions to a few hundred thousand per cu. ft. When a respirator was used with a helmet and positive pressure, a further material reduction resulted. It was recommended that, where workers must be within sand blasting cabinets, they be protected by helmets with positive air pressure and with respirators of the type described.

---

* Report of the Committee presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 19, 1928.

In a study[4] of the dust hazard in an ax-grinding factory, it was found that in Connecticut, 1900 to 1918, the death rate due to tuberculosis was about ten times higher among polishers and grinders than for the male population of the state. Winslow and Greenburg[4] quote many authors who recommend wet methods of grinding for lessening the dust hazard. They conclude that wet grinding, as practiced in the factories studied, is extremely dangerous, and that the substitution of dry grinding with an efficient filtering system, or wet grinding on harder artificial abrasive wheels, is clearly indicated as a measure for protection of workers against respiratory disease.

In 1921 a study similar to that in the Joplin and Butte districts was made by the U. S. Bureau of Mines among gold miners of Nevada. Of 303 miners examined, 51 were negative; 8 doubtful; 141 were in the first stage silicosis; 69 in the second; and 34 in the third stage. Among 181 gold miners of California examined in 1921 and 1922, 68.5 per cent were negative; 24.8 per cent had silicosis in some stage; 6.7 per cent were doubtful; and 4.4 per cent had tuberculosis. No sputum examinations were made, as the cases had progressed to such a stage that the condition could be easily determined clinically.

In a statistical study of the granite industry about Barre, Vt., Hoffman[5] found that during the period under observation the mortality from pulmonary tuberculosis increased from 257.7 per 100,000 in 1896, to 953.4 in 1918 (a maximum of 1,330 having been reached in 1916). During this same period, the mortality of the general population declined from 207.5 in 1896, to 96.4 per 100,000 in 1917, excluding, in the case of the granite workers, the last few months of 1918 on account of the influenza epidemic.

The U. S. Public Health Service has undertaken studies planned to cover the entire field of the dusty trades in the hope of contributing to a better understanding of certain unanswered questions.[6] The following were selected:

1. The cement industry, representing calcium dust
2. Silver polishing, representing metal dust
3. The granite industry, representing silica dust
4. The hard coal industry, representing carbon dust
5. The cotton industry, representing vegetable dust
6. Street sweeping, representing municipal dust

The first of these studies has been completed, and the report published as *Public Health Bulletin No. 176.* The investigation was conducted in one of the older, dustier plants, so that the effect of large quantities of the dust could be observed. Records of all absences from work were kept for 3 years, and the nature of disabling sickness

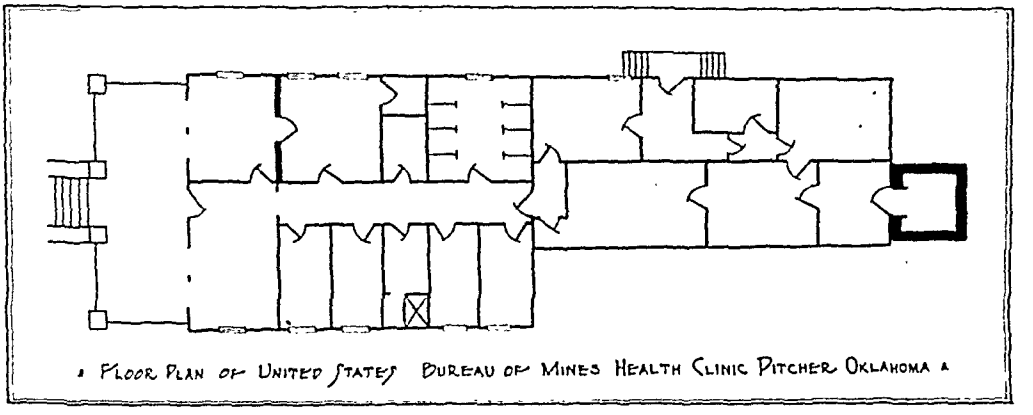
was ascertained. Physical examinations were made, X-ray films were taken, and the character and amounts of dust in the atmosphere of the plant determined.

The results indicated that the calcium dusts created in manufacturing Portland cement do not predispose workers to tuberculosis nor to pneumonia. The exposed workers experienced, however, an abnormal number of attacks of diseases of the upper respiratory tract, especially colds, acute bronchitis, inflammations of the pharynx and tonsils, and influenza. Attacks serious enough to cause absence for two consecutive working days, or longer, occurred among the men in the dustier departments at a rate about 60 per cent above that for the men in the comparatively non-dusty departments. Limestone dust appeared to be slightly more deleterious than cement dust. Outdoor work in all kinds of weather, such as experienced by the quarry workers, appeared to predispose to diseases of the upper respiratory tract even more than exposure to the calcium dusts.

Of 309 miners of the Tri-State District, Picher, Okla., examined by the U. S. Bureau of Mines in 1923, 101 were negative, 114 doubtful, and 94 positive for silicosis; 52 of the 94 were in the first, 22 in the second, and 20 in the third stage. Following this study, a clinic was established at Picher, the building, heating and lighting being supplied by a local organization. The number that could be examined at the clinic was limited, as only one surgeon was available.

In all the investigations referred to, only a part of the men in any industry were examined. The percentage of those found to have silicosis among the men examined was probably greater than for the total number employed, due to the tendency of those who have symptoms to apply for examination, while the apparently healthy worker does not inconvenience himself to come in.

In addition to the physical examination of miners, surveys of the conditions under which they work, especially as to dust, have been made in most of the studies mentioned. Based on the data collected by the physician and the engineer, the following recommendations are usually made:



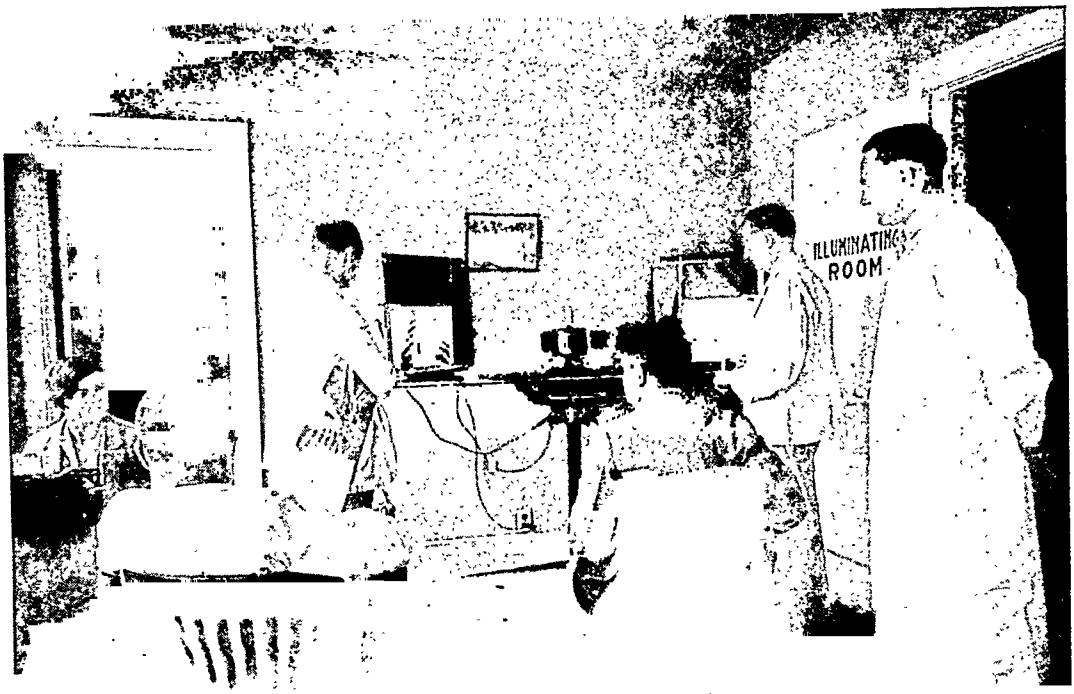
1. That good ventilation be provided to supply air free from dust to all workers.

2. That wet methods be used to lessen the formation of dust and to prevent it entering the air when once formed.

3. Physical examination of all applicants for work in positions where dust exposure exists, with rejection of those having tuberculosis. This rejection is to prevent exposure of healthy workers to the infection, as well as to protect the applicant from any harmful effect from the dust. Periodic examination of all

workers to determine the earliest detectable signs and symptoms of silicosis or tuberculosis should be made.

All men should be informed of the findings and those having tuberculosis removed from exposure to siliceous dust and from contact with others exposed to siliceous dust. Those having simple silicosis should be permitted to make their decisions as to continuing at the work after they are informed of the meaning of the findings.



FLOOR PLAN OF UNITED STATES BUREAU OF MINES HEALTH CLINIC PITCHER OKLAHOMA

In the industries in which studies have been made, at least some of the recommendations have been adopted. However, there is no provision for compulsory physical examination of all applicants for work nor for periodic examination of all employees. In 1927, the U. S. Bureau of Mines clinic at Picher, Okla., through coöperation with the Tri-State Zinc and Lead Ore Producers Association and the Metropolitan Life Insurance Company, was enlarged to provide for the examination of all those employed in mining in that district. A special building was constructed, with waiting room, clinical office, four examining rooms, X-ray and developing rooms, X-ray storage vault, dressing rooms, illuminating and conference room, and an office for the physician in charge. In addition, two rooms are provided for the welfare nurses of the district. Figure I shows the floor plan of the clinic.

The personnel of the clinic consists of 4 physicians, an X-ray technician and assistant laboratory technician, chief clerk, 3 stenographers, and janitor.

A standard routine has been developed for examination. On entering the building, a detailed personal and occupational history* is taken. The miner then goes into the dressing room where he undresses and puts on a bathrobe; passes to the X-ray room, where a picture of his chest is made; and then to the photographic room, where

* Copies of the form used may be obtained from U. S. Bureau of Mines clinic, Picher, Okla.

a photograph of his face with his name is made on an identification card (to prevent substitution). He is then given a complete physical examination, special attention being given to the chest, and any defects noted on the history sheet. He next goes to the laboratory for routine blood examinations (Wassermann and Kahn) and, if thought necessary, differential count, stomach analysis, and any additional work desired by the examining physician. The history, containing results of physical examination, laboratory work, and the X-ray pictures, is assembled, read, interpreted, and a diagnosis made. All physical defects are noted and the man given one of the following classifications:

A. Physically sound in so far as can be detected.

B. Average, with such minor defects as slight error in vision or hearing, chronic catarrh, enlarged turbinates and enlarged tonsils, slightly more fibrosis than normal in lungs, large open rings, slight varicose veins, slight varicocele, ingrowing toenails, fat tumors, overweight or underweight, small piles, and such deformities as missing finger, or other deformities that do not interfere with work.

C. Small errors in vision and hearing, very bad teeth, slight rheumatism, silicosis, first degree, moderately bad hemorrhoids or piles (bleeding), moderately bad varicose veins, varicocele, missing fingers, stiff joints (with deformity functioning); certain diseases of the heart, graded C for certain occupations, principally those that will not endanger the man on sudden exertion; also malformations of body that permit of work, as flat feet, beginning goiter, large scars, new growths, psoriasis, eczema, and other diseases that do not seriously interfere with working efficiency or increase the accident hazard, or are not liable to cause sudden death.

D. Seriously defective eyes, hearing, marked rheumatism, deformities, malformations, scars, etc., that seriously interfere with the working capacity; diseases of the heart (liable to cause sudden death), epilepsy, syphilis, gonorrhea, asthenia, very bad varicose veins (with ulcers), cancer in early stages, silicosis, second degree, all contagious diseases, body lice and other vermin, mental defects, and all other diseases considered dangerous to the health of a man employed underground or that will increase the hazard to other men working underground with him.

E. Practically blind or deaf, severe heart lesions (in the last stages), third degree silicosis, severe syphilis, gonorrhea, and all diseases that are liable to terminate in sudden death.

F. Beginning tuberculosis, tuberculosis associated with any of the above diseases, or the closing stage of any of the above diseases.

G. Moderately advanced tuberculosis, moderately advanced tuberculosis complicated with one or more of the diseases previously referred to, or two or more of the diseases previously referred to in advanced stage.

H. Advanced tuberculosis alone or complicated with other diseases.

I. Beginning tuberculosis complicated with silicosis or with some other similar disease that would seriously jeopardize the chances of recovery.

K. Third degree silicosis complicated with advanced tuberculosis.

Men classified A, B, or C are recommended for employment underground, but when those in the C class have certain diseases the card will state " C classification for certain occupations only."

During the fiscal year 1927–1928, the clinic examined 10,427 subjects. The number employed in the mines normally is about 10,000; at present about 7,000 are employed.

Establishment of Division of Infant Hygiene in Mexico

A DIVISION of infant hygiene has been established in the Federal Department of Public Health of Mexico. This division will organize infant-hygiene centers, first in Mexico City and later in other parts of the country, for teaching mothers infant care.—*El Universal*, Mexico City, Jan. 22, Feb. 3 & 5, 1929.

Discharge of Filtered Sewage into an Otherwise Unpolluted Stream*

HARRISON P. EDDY, FELLOW A. P. H. A.
Metcalf & Eddy, Engineers, Boston, Mass.

THE sewage of Brockton, Mass., receives treatment at a plant located in the southwestern part of that city near the line between the city and West Bridgewater. The treatment plant consists of sedimentation tanks, trickling filters and sand filter beds. The effluent is discharged into the Cowesett Brook, which in turn is joined by the Ames Stream, coming in from the west, the two forming the Hockomock River.

The water supply of Brockton is derived from a watershed not tributary to the Hockomock River. It follows that the discharge of sewage effluent into Cowesett Brook increases the natural flow of that stream and of the Hockomock River in proportion to the quantity discharged.

It is claimed by lower riparian farmers that as a result of the discharge of effluent into the stream there is in summer such stimulation of aquatic growths along the banks and in the bed as to retard greatly the combined flow; and, further, that the increase in normal discharge, with the obstruction of the channel, results in the maintenance of such high ground water levels in certain low lands bordering the streams as to render them practically worthless for agricultural purposes.

Action to recover damages was brought in the Superior Court of Plymouth County by a group of riparian owners. An auditor was appointed by the court, who heard the evidence and made a view of the Brockton sewage works, streams and lands involved. The report of this auditor was presented recently to the court, and a review of the case is of considerable interest from the standpoint of the sanitary engineer.

Below the junction of the Ames Stream and the Cowesett Brook, the Hockomock River flows in a general southerly direction for several miles, then turns east to form, with Nippenicket Brook, the Town

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 19, 1928.

River, which flows east, then south, until it joins the Taunton River, which in turn empties into Narragansett Bay. The upper portion of the watershed above West Bridgewater is gently rolling farm land upon which are scattered several small villages, none of which is supplied with a sewerage system. Along the lower course of the Hockomock and in the vicinity of the Nippenicket Pond, from which the Nippenicket Brook flows, there is an extensive area of low land known as Great Cedar Swamp. The watershed areas of the several streams above certain significant points have been determined from the U. S. Geological Survey maps as follows:

Cowesett Brook at confluence with Ames Stream, 7.9 square miles
Ames Stream at confluence with Cowesett Brook, 9.6 square miles
Hockomock River at West Center Street, 20.1 square miles
Town River at Ames Dam, 52.8 square miles

HISTORY OF THE USES OF THE HOCKOMOCK RIVER

For many years the Ames Stream and Cowesett Brook have been used as sources of water power, and dams and mills have been constructed upon them. The milldams on the Cowesett Brook have ceased to function as such, but the small ponds formed thereby are used for ice harvesting. The Ames Stream is still used to some extent for water power. In the Town of Easton, the Ames Agricultural Implement Company maintains a small shovel mill operated by water power, which has been in existence for many years. The water of this stream is again used for power at three different points. Below the Ames Company two other water powers are utilized during four or five months of the year. No milldam or pond occurs below the junction of the Ames Stream and the Cowesett Brook until the Village of West Bridgewater is reached, about 10 miles downstream, where there is an old dam called the Ames Dam, located across the Town River.

The stream and its tributaries have been used for water power for many years and the flow controlled according to such use, this being by riparian owners and within their rights. The utilization of the streams for power is of significance in connection with the claims and counterclaims during the legal proceedings described later.

Brockton Sewage Treatment Plant—In 1893, the city of Brockton began the construction of a sewerage system and in 1894 a sewage treatment plant consisting of intermittent sand filters was built. These were located in the extreme southwest corner of the city and the effluent discharged into Cowesett Brook. The present plant consists in part of the original filters, with sedimentation tanks and trickling filters constructed during the past 16 years.

The sewage flows at Brockton have in general steadily increased from about ⅓ m.g.d. in 1896 to over 3½ m.g.d. in 1927. This fact is of particular significance as regards the changes in the character of Cowesett Brook and Hockomock River by the discharge of sewage effluents.

Effect of Discharge of Brockton Sewage Effluent—The first effect of the discharge of the effluent is to increase the normal flow of the streams into which it enters. In winter, this is materially less in proportion than in summer, due to the greater natural run-off. The effect is proportionately less in a wet than in a dry year. The proportions of effluent in the Cowesett Brook below the treatment plant for the months of July to October, inclusive, 1923, computed on the basis of data presented during the hearings, are given in Table I.

TABLE I

PER CENT INCREASE IN NORMAL STREAM FLOW DUE TO DISCHARGE OF BROCKTON SEWAGE EFFLUENT

1923 Month	Sewage Flow c.f.s.	Normal Stream Flow Cowesett Sta. 4 c.f.s.	Normal Stream Flow Hockomock Sta. 5 c.f.s.	Per Cent Increase due to Sewage Effluent at Sta. 4	Per Cent Increase due to Sewage Effluent at Sta. 5
July	3.92	2.22	9.78	177	40
August	3.18	1.56	7.89	204	42
Sept.	3.11	0.75	5.43	415	57
Oct.	3.02	2.29	9.98	132	30

It will be seen that in the summer of 1923 a large proportion of the average monthly flows of Cowesett Brook and Hockomock River consisted of effluent from the Brockton plant.

One of the most serious effects of effluent, as claimed by the plaintiffs, is the stimulation of aquatic growths and the resultant clogging of the channels by the growths and by banks of silt and sand, the formation of which is fostered by these growths. Plant growths are stimulated by nitrogen in the form of nitrates and by carbon dioxide, both of which are present in considerable quantity in sewage effluents. The very heavy growth of vegetation in the Hockomock River below the plant at Brockton aggravates materially the effect of the augmented stream flows.

The combination, therefore, of channel obstruction with abnormal flow during the summer months results in the maintenance of high water levels in the stream and high ground water levels in the low lands along the stream so that it is impossible to secure proper drainage of these lands. Much of the land adjacent to the stream is subject to flooding under normal conditions in winter and spring, but in summer in earlier years has been cultivated and crops grown thereon.

Another effect of the discharge of sewage effluent has been to change the physical appearance of the stream as regards color and turbidity. In the early days of operation of the intermittent sand filters, the effluent was practically clear and colorless and had little effect upon the stream into which it was discharged. As these filters became inadequate to care for the entire sewage flow, trickling filters were built, part of whose effluent after sedimentation was discharged directly into the stream, and part upon sand beds. The turbid character of that part of the effluent not passed through the sand beds brought about an increase in turbidity and color in the stream receiving it. Above the entrance of the sewage effluent, the stream is ordinarily clear, with a slight natural brown color, and odorless. Below, the stream became gray or gray-brown in color, turbid, and at times slightly odorous. The character of the stream bottom changed from clean sand or gravel to black humus-like material, and at times masses of worms similar to those found in trickling filter media were noted.

Analyses have shown a marked increase in organic constituents and in bacterial content in the stream waters below the treatment plant. The organic matter has been sufficient in summer to bring about a marked reduction in the dissolved oxygen content of the stream. Such reduction, however, has not been sufficient to bring about putrefactive conditions of the stream water. Offensive conditions, however, have been caused, due to the stimulation of large growths of duckweed which at times have collected in masses, died and decayed, with the production of offensive odors.

Hearings before Auditor—During the hearings, which consumed about 20 days, much evidence, both technical and lay, was presented by plaintiffs and defendants. Some of this is summarized in the following paragraphs:

The sewerage system and method of sewage disposal adopted by Brockton were authorized by an Act of the Massachusetts Legislature in 1890.* Section 2 of this Act referring to the Board of Commissioners of sewerage construction authorized by the Act reads in part: "said Board of Commissioners shall have exclusive authority to construct, maintain and operate the system of sewerage and of sewage disposal adopted by the City Council. . . ."

On May 28, 1890, the City Council of Brockton adopted a system of sewage disposal in an order reading as follows: "Ordered, that a system of sewerage be, and the same is hereby adopted for the whole territory of the City of Brockton, with mains, pumping stations and

* Chapter 248 of the Acts and Resolves of 1890 of the Massachusetts General Court.

irrigation lands, as may be necessary to successfully operate a system of sewage disposal by 'downward filtration,' which system of sewage disposal is also hereby adopted."

This order, and particularly the description of the system of sewage disposal as "downward filtration," assumed some importance in the course of the case. It was claimed by the plaintiffs that the trickling filters did not comply with the original plan and scheme adopted and authorized by the city council. No record of the adoption of any other method of disposal was produced by the city. The plaintiffs' contention that there was a departure from the original plan and scheme was based upon the interpretation that in 1890 the term "downward filtration" referred to intermittent sand filtration, that trickling filters had not been devised at that time and being a subsequent invention could not have been the method of sewage disposal then adopted. The defense claimed that "downward filtration" was a general term applicable to any kind of filtration, trickling filters or intermittent sand filters. The plaintiffs in turn pointed out that in the records of the original order the term "downward filtration" was set off by quotation marks, showing that a specific kind of filtration was meant and that the intermittent sand filters installed were in compliance with the meaning of the order. The contention of the plaintiffs in this matter was upheld by the auditor in his report.

It was brought out that in time the original filter beds became overtaxed, resulting in a deterioration in the quality of the effluent. Due to the inadequacy of available areas for extension of the sand beds, it became necessary to adopt a different system of treatment. After studies and experiments trickling filters with preliminary and secondary sedimentation tanks were adopted by the sewage commission but without formal adoption by the city council.

From the correspondence passing between the city authorities and the State Health Department, it appeared evident that treatment of the final effluent from the trickling filters upon the old sand beds was contemplated. As a matter of fact, certain of the sand beds were set aside for this purpose but, as was brought out in the testimony, only a portion of the trickling filter effluent was thus treated, although steps were under way to make available more sand bed area so that the entire trickling filter effluent could be treated thereon. The auditor found that if the trickling filter effluent were passed through the sand beds, the city would be treating the sewage in accordance with the original method adopted by the city council in 1890 but that it failed to treat according to the method adopted when trickling filter effluent was discharged directly into the stream.

Evidence was given to the effect that stimulation of aquatic growths would occur whether trickling filter effluent or sand bed effluent were discharged, and that good sand bed effluent might result in even greater stimulation of growths due to its more highly nitrified character.

The defense claimed that the regulation of the Ames Stream for power purposes was an important factor in the maintenance of high water levels in the Hockomock River but presented as evidence a maximum observed effect of only about 6 inches at the property of the owner of the largest areas involved. As power regulation had existed for many years, the contention that it was a material factor apparently received little attention on the part of the auditor.

It was difficult to estimate the rise in water levels as a result of the obstruction by excessive aquatic growths. This difficulty was due in part to the fact that no hydraulic study of the stream had been made prior to the time it became affected by the vegetation. Furthermore, the course of the stream is meandering and its cross-section varies materially from point to point, making hydraulic measurements of doubtful significance. Based on judgment and a few actual measurements, it was estimated by the engineers for the plaintiff that the normal water level in the stream during the summer months had been increased from 1½ ft. to 2 ft. by the excessive vegetation in the stream. This estimate was accepted by the auditor, who found that the land involved had been rendered worthless as a result of the increase in water levels resulting directly and indirectly from the discharge of the effluent from the Brockton sewage treatment works. The several plaintiffs were awarded damages amounting to the fair market value of their lands as of 1914 together with interest from the date of the writ.

CONCLUSION

This case is illuminating as to the results which may follow the discharge of effluents from sewage treatment plants into streams where the natural flow available for dilution compared with the volume of effluent is small. Two lessons are taught: (1) Well purified effluents require substantial dilution. (2) Extensive easements may be necessary where adequate dilution is not available.

Steps in Planning a Health Education and Publicity Program*

The Facts—How to Decide What Is to Be Told

C.-E. A. WINSLOW, DR. P. H., FELLOW A. P. H. A.

Professor of Public Health, Yale School of Medicine, New Haven, Conn.

IT IS my special function to discuss the factual material to be used in this campaign, to suggest criterions by which we may select the particular things which we wish to tell the world. This is, after all, a somewhat important consideration if publicity is a means and not an end in itself. The points we select should be true, important, comprehensible, acceptable, and usable.

First, our facts should be facts. All truth is relative, but we can at least strive to escape the cruder errors of the past. We can avoid giving the impression that litter and paper in the street and in the back yards are likely to produce disease; that dust is a fertile source of infection; that dental caries bears an inverse relation to the use of the tooth brush twice a day. On the other hand, we should not be too eager to introduce into our programs of popular education the newest suggestions of science before they have become established and accepted. We should be careful about advocating the indiscriminate use of iodized water or salt, or of scarlet fever serum as preventives. We should be cautious as to our statements regarding the relation between neglected tonsils and infections of the heart. These, and many more things which are interesting us at present, may prove to be true; but only after thorough thrashing out of all opposing scientific points of view should we shout the conclusions of science into the public ear. As Polonius tells us—" Be not the first by whom the new is tried, nor yet the last to cast the old aside."

In the second place our facts should be important. The statement of even an unquestioned truth with over-emphasis may often prove misleading if we do not bear in mind the relative proportion of different truths and their probable effect upon the public mind. It

* Papers from a symposium of the Public Health Education Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17 and 18, 1928. Papers by Mary Swain Routzahn, Howard Whipple Green, and Marjorie Delavan appeared in May, 1929, JOURNAL.

is true that clean milk is better than dirty milk and for children it is probably more healthful. It is probably true that tuberculin testing of cattle is a useful mode of protecting these animals against one of their commonest and most serious diseases. It is not, however, true that clean milk from tuberculin tested herds is necessarily or probably safe milk for human consumption. There is only one safe milk—that which has been made safe by heating. This is the important fact for the public to know and, if emphasis on the other and lesser facts obscures this one, we are doing harm and not good.

In our program of public health education as a whole we may properly ask for something even more than accuracy of emphasis in regard to each particular problem. We may also demand that each problem emphasized be set into a general scheme which will make for a comprehension on the part of the public of the broad and fundamental principles which underlie the promotion of health and the prevention of disease. There are, I believe, some dozen such principles which we should like every member of the community to grasp, and we may properly consider how each element in our educational plan contributes toward building up these basic attitudes.

We must, for example, make sure that our educational program as a whole tends to further an understanding of the established elements in personal hygiene. We want our public to understand the importance of diet as a basis of sound health, an importance which we are realizing more and more fully with every passing year. There are few things which would accomplish more for health promotion than an increase in the consumption of milk, fruits and green vegetables; and the change in the dietary habits of a whole population, accomplished at Fargo as a result of well planned health education in schools, is one of the most significant accomplishments of recent years. We want our public to understand the rôle of cool, moving air as a factor in the hygiene of the skin and as an important element in promoting resistance against respiratory infections. We must emphasize the value of exercise and the hygienic significance of sleep and rest. We must keep in view the novel, and as yet only half understood, principles of mental hygiene. In this field we are not only missing invaluable opportunities, but we are often perhaps doing positive harm. I once saw a poster representing a foreman administering to the worker with a large spoon "His daily dose of lead." Such a poster tends to create mental disease more than to control industrial poisoning.

Our main objectives should also look toward a comprehension of the ways in which communicable diseases are spread and in which they may be controlled by the protection of water and food supplies, the

elimination of insect carriers of disease by isolation and quarantine, and by such habits of personal cleanliness as tend to guard the gateway of the mouth. Above all, we must work for a real comprehension on the part of the public of the principles of vaccine and serum therapy.

Still another set of principles which should be basic are those which deal with the relation between the physician and the patient. We should do everything that we can to build up the idea that the physician is a trainer and not a repair man, and to show how, from the prenatal period through infancy and school life, in industry and in the decades of degenerative disease, the principle of health examination is essential to a maximum of health and efficiency.

Everything that we include in our health education program should consciously lead toward the building up of a knowledge of principles of healthy living, and this program should be so organized as to cover them all with reasonable completeness in any period of a year.

In the third place, the facts we teach should be comprehensible to the man in the street, and not merely to the statistician, physician, or sanitarian. Statistics addressed to the general public should be simple and obvious in their bearing. Lists of the number of cases of communicable disease occurring in a city or state during a given week have a charm which is beyond my personal comprehension, but which is clearly indicated by the eagerness with which newspapers give space to bulletins of this sort. From the public health standpoint, they are almost meaningless, but they apparently appeal to the average reader like the box score of a baseball game. They give the impression that something is happening. They form current news. On the other hand, proportions and averages mean little or nothing to the average reader. When one reads, as in a recent city bulletin, " . . . about 3 out of every 5 children less than 6 years old can catch diphtheria, and about 2 out of every 5 children between 6 and 10 years of age can catch this disease," the average reader with a 13-year mentality is absolutely " sunk." Specific individual cases with the human appeal carry far more effectively than most statistics, and many visiting nurse associations are obtaining splendid health publicity with data of this kind. In general, our material should be simple and concrete, and our programs so planned that one lesson at a time may be hammered in, before the public mind is confused with some different and perhaps conflicting issue.

The fourth of our criterions is, that the facts we select for our educational program should be emotionally acceptable. If we are to accomplish results, it is essential not only to catch the interest of the hearer but to arouse in him a desire to attain the aim set forth.

There must be motivation as well as intellectual conviction. In considering this aspect of the problem we should lean more heavily than we have done upon the psychologists and professional educators.

Finally, as our last criterion, it is perhaps scarcely necessary to emphasize that the facts which we teach should be usable. In dietary instructions it is not of particular value to urge the drinking of milk in a southern industrial community if no milk can be obtained. It is futile to advertise toxin-antitoxin treatment of children unless there are clinics where the treatment can be administered. It is useless to urge an adult to go to his physician for a health examination, unless there is some reasonable probability that when he goes he will get one.

SUMMARY

The object of our whole program is, I take it, to change the conduct of individual men, women and children. We want them to manage their bodies well; to help us check communicable disease; to use preventive medical service; and to support the community program of health promotion. In the factory, it is possible to analyze every industrial operation into the simple exposure form of a raw material to a tool or a process with the production of a finished product. Our raw material is ignorant human nature; our finished product is the citizen trained in healthy living. Our tools are our bulletins, newspaper articles, lectures, radio talks, and cinema showings. The facts that they teach must be true and important or the educational process will not be worth the cost. They must be comprehensible, acceptable, and usable, or there will be no effective educational process at all.

We are interpreters between the vast resources of health science on the one hand and the individual in the home and the factory on the other. We must keep both things in view. We must believe in both. We must have faith in the message we deliver. As Richard Cabot once said, I think, of social service, we must feel that we have something " too hot to hold." We must also believe in the educability of the common man, or our efforts will be spiritless and futile. It is these two faiths after all—faith in the cause, and faith in human nature—which make the health educator. Whatever our technic, whatever our rigidness of self criticism, we must add at the end that quality of enthusiasm—a word which in its derivative sense means an inward god. The work of translating the lessons of science into human conduct is indeed a godlike one. If we fully realize its significance, we shall not fail.

The Approach—How to Decide on the Motives for Conduct to Which an Appeal Will be Made

FRANKLIN FEARING, PH. D.

Department of Psychology, Northwestern University, Evanston, Ill.

BROADLY speaking, there are but two fundamental questions which may be asked regarding human behavior: *How* do individuals act as they do—what are the mechanisms and processes involved in behavior? and *why* do people act as they do? It is with the latter question that we are primarily concerned in the present discussion. Attempts to answer this question have been made since man first speculated regarding the origin and causes of his own acts. A completely satisfactory answer would imply the ability to predict individual action on the one hand, and the ability to control or modify it on the other. We must confess that such an answer is not forthcoming in the present state of our knowledge; the claims of the pseudo- or itinerant-psychologist, the phrenologist, and the quackish fraternity in general to the contrary notwithstanding. While the advance which modern psychology has made in this field does not enable us to manipulate individual action with certainty, it offers data which are suggestive to those who are concerned with problems of direction and control of public opinion, and the modification of individual action.

What is the nature of those inner or outer factors which determine and control our behavior in given situations? Why, for example, do I turn my head toward the source of a sudden loud sound, stop my automobile when the traffic light flashes red, stand up when the national anthem is played, vote for a particular presidential candidate, or read a paper before a scientific association? The blanket term " motives " may be applied to all those factors or mechanisms in the organism which determine my response in these or other situations. A motivated response, then, is one which is determined primarily by conditions or factors within the organism. Knowledge of the nature of these factors is of the greatest significance to all those interested in the modes of effective appeal with a view to modifying human action.

There have been those who would say that these inner factors or motives are primarily rational and logical in nature. It is assumed that man is possessed of nicely tied-up packages of knowledge, called ideas, as a result of experience in the world, and after a preliminary

period during which these ideas are compared and arranged, reasoned and logically determined actions result. Furthermore, it is assumed that some of these ideas carry with them a kind of inherent rightness or soundness—as though they were certified checks—which will be instantly recognized by all reasonable and right thinking persons, and hence will lead to sound judgments and reasonable behavior. I am, for example, presented with a leaflet on which is emblazoned the statement that "Heart disease, after age 40, heads the list of causes of death in the United States," with the accompanying suggestion that death from this disease can be reduced by early diagnosis and treatment. As a bit of presumably authoritative information, this statement is interesting, but it carries no guarantee that it will stimulate rational thought which will lead to desirable action in the form of periodic physical examinations. At best it will arouse a mildly disturbing fear reaction.

The conception of human action as motivated by conscious rational processes presents an artificial and unreal picture of behavior. It is true that we rationalize our behavior after the acts have taken place. It is true also that in certain restricted fields, for example, science, rational processes probably occur before action. But it is one of the most certain conclusions of modern scientific psychology that in the vast majority of our actions there is little in the way of preparation that may be included under such terms as reasoning, judging or thinking. A publicity program based exclusively on the assumption of rational motivation in human action cannot be expected in the long run to yield satisfactory results.

A second assumption regarding the controlling factors in action is that the organism responds in a more or less mechanical way to external stimuli. From the point of view of this conception the "right" stimuli will inevitably release the "right" responses. For example, correct information or positive instruction regarding prevention of disease is expected to lead to positive and desirable action. This will not occur unless the information or instruction is arranged to appeal to motivating factors within the individuals to whom the appeal is directed.

It is with the nature of these motivating factors that we are concerned in organizing and presenting publicity material which is designed to modify human action. My reaction to the names Herbert Hoover or Alfred E. Smith or Norman Thomas is not explained by those words as merely auditory or visual stimuli, or even by the purely intellectual considerations of what I am told is their position on the tariff question. My reaction, in so far as it has drive and intensity,

is determined by the appeal which those names, as symbols, make to certain fundamental, non-rational reaction patterns or tendencies to action. These reaction patterns or mental sets, many of which were acquired in childhood, furnish a background and are the source of the drive for most of the activities of the individual. Some of these may be inherited, but most of them are acquired by a process of social conditioning. They are called attitudes and may be defined as the more or less persistent tendencies by reason of which the individual is rendered particularly susceptible to certain kinds of situations.

I may have, for example, a strong attitude regarding animal pets —dogs in particular—which will determine in large measure whether I shall enthusiastically support or resist an attempt to enforce a measure to muzzle dogs in an antirabies campaign. It may be that my somewhat undiscriminating affection for dogs will cause me to view the entire campaign in the light of an unwarranted persecution of these animals. This may lead to an active resistance to all attempts to muzzle my own dog and an attempt to organize public sentiment against the measure itself. On the other hand, a deep-seated fear of dogs may cause me to see a mad dog in every panting animal met in the street. These attitudes may have existed over a long period of time and possess an intense emotional coloring, or they may have been established by a single recent experience. For example, the sight of a dog chasing a child, or an instance of a neighbor's child being bitten, or the report of my own child that he has been attacked by a dog, may serve to set up an attitude which will determine my response to any type of stimulus which relates to dogs. In these instances we have action determined by processes in which reason and logic play little part.

Attitudes of a more general type are illustrated by one's reaction to such topics as immigration, prohibition, socialism, Bolshevism, etc. In these cases the attitudes are released or " touched off " by a wide range of stimulating situations. Our attitude toward Bolshevism, for example, may determine our behavior toward Russian art, the Russian ballet, Lenin, whiskers and Tolstoi.

A striking characteristic of attitudes of the latter type is the facility with which they become attached to symbols. These symbols, or stereotypes, as they are called, are illustrated by our conception of a bewhiskered Bolshevist throwing a bomb, the absent minded college professor, the excessively collegiate college student, the long haired poet, the excitable Frenchman, the phlegmatic Britisher, and so on. These stereotypes frequently symbolize our attitudes toward certain individuals, groups, or races, or they may represent our atti-

tude toward an idea or principle. They are of the greatest significance to those who are concerned with the control or modification of individual action for the reason that by means of pictures or in other ways, it is possible to appeal to the attitudes of the individual through his stereotypes.

This appeal is possible because, to a large extent, the stereotypes which the individual holds determine the nature of the impressions which he gets from the world about him. My stereotype of the Englishman expresses my antagonism and hatred, or my affection and respect; in either case it acts as a selective factor so far as my impressions of Englishmen are concerned. These stereotypes may be formed as a result of a slow accretion of impressions over a long period of time, or they may be formed as a result of systematic propaganda. When they represent the collective attitudes of a group, they may compel the object of the stereotype to conform to the picture. For example, the American stereotype of the youthful aviation hero compelled its object, Lindbergh, to conform or " fit into " the picture. The creation of these stereotypes is one of the great games of the publicity agent, as a result of whose activity we may have the " strong silent man in the White House," the " people's friend," the " great humanitarian," and the " happy warrior."

We may briefly summarize the characteristics of attitudes and point out their significance to those who are trying to modify the conduct of men, women and children. Attitudes as factors in human action may be characterized as follows:

1. *They tend always to express themselves in action.* They are potential actions. In fact, they may be said to exist only in so far as they do obtain overt expression. The individual from one point of view may be regarded as constantly seeking situations in which these attitudes may find satisfying expression.

2. *Attitudes tend to have a strong emotional coloring.* They have their roots in our likes and dislikes, our fears, hates, and joys.

3. *Attitudes do not involve rational processes as an antecedent to action.* Deliberative action involves a balancing of the issues and tends to inhibit or at least retard action. Actions which involve major attitudes tend to be immediate and intense.

4. *Attitudes may be conscious or unconscious.* That is to say, I may recognize and identify my attitude or I may fail or refuse to recognize that my actions are motivated by a particular attitude.

5. *Attitudes are associated with and easily released by symbols, signs, slogans, phrases, catch-words and pictures.* The individual tends to build up a stereotype or mental picture in which the attitude is personalized and characterized in graphic form. Newspaper cartoons make large use of this mechanism in appealing to group attitudes. Slogans almost always appeal to attitudes. Whoever stops to analyze intellectually a slogan? It is what the slogan implies or suggests that makes it effective.

6. *Where fundamental attitudes are involved, the response is out of proportion to the intensity of the stimulus.* The wild enthusiasm incited by the appearance of a brown derby can scarcely be accounted for in terms of the brown derby as a visual stimulus.

7. *Attitudes may be developed as a result of a single experience, or they may be established by systematic and persistent propaganda.* An example of the first is the establishment of an intensely negative attitude toward a given race as a result of a single unpleasant experience with a representative of that race. In the second case my attitude towards public health may be established as a result of the continuous presentation of materials arranged in dramatic and dynamic settings, suggesting success, prestige, happiness and efficiency.

The significance of attitudes to those interested in a program of health education is obvious. The objective of such a program is the modification of conduct of men, women and children with regard to what might be termed " health behavior." Such a change in conduct cannot be effected except through a change in attitudes.
